JOURNAL OF THE TELEGRAPH.

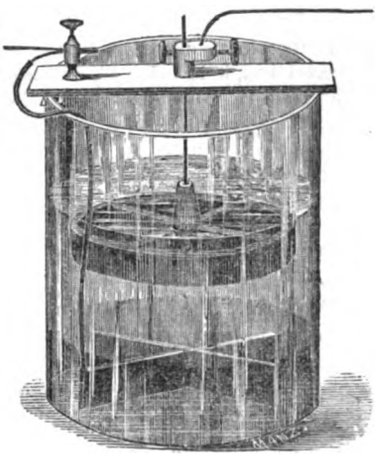
VOL. V. NO. 1. NEW YORK, DECEMBER 1, 1871. WHOLE NO. 98.

ELECTRICITY AND THE RAILROADS.

The grand Central Depot at Forty-second Street, New York, was opened to business on Wednesday, November 15. The opening was signalized by the test, in the hands of Mr. Toucey, Superintendent of the Hudson River Road, of a system of electric signals devised by him, by which one man will control the movements of all locomotives and trains in the vicinity of the depots.

A signal room is at the centre of the north wall. A large number of electric keys are arranged on a table, connecting with gong bells and disks in the depot, and in a round building 100 feet north. The disk signals within the depot are displayed from three round cases over the door-ways of the north wall, beneath which hang the bells. There are bells also in the passenger and baggage-rooms, rung by the electric apparatus. Twenty minutes before a train is to leave, two taps of a bell instruct the door-keeper of the passenger-room of the road to which that train belongs, that it is time to allow passengers to enter the cars. Five minutes before the time of departure, three taps on the bells give warning. One tap at the exact time for leaving, is a signal to close the doors. Nine of the keys on the table are used for signaling the interior operations of the depot—three for each road.

The signal-house outside the depot, is a curious building, displaying on its north and south sides, sixteen glass bull's-eyes, each a foot in diameter. The bottom row contains six windows, the second six, the third three, and a single bull's-eye is over all. The twelve lower windows are for the instruction of the switchmen. When a train is signaled from the junction, the signal-man at the depot, touches a key on his board that causes a number to appear in one of the bull's eyes, and at the same time rings a gong hanging on the signal-house. The number indicates the switch to be prepared for the incoming train. The three bull's-eyes in the third row are colored disks. When one turns up at the same time that the gong rings, the engineers of that "color" know that one of their engines is wanted. Three strokes upon a certain gong, one minute before the time of departure, instruct the engineer to back into the depot and fasten upon the train. Besides the keys mentioned, there are several others on the board. Two are to indicate whether trains are to be stopped at Fifty-sixth street or not, and two are to inform engineers whether they shall unhitch their engines from incoming trains, or draw them into the depot.



A device has also been adopted by which every train, as it passes out at the upper end of the Yorkville tunnel, touches a spring and sends back an electric current, ringing a bell in the signal-tower, informing the operator that the way through the dark passage is all clear. Coming into the city, from the junction at Mott Haven, every train regulates the signals to be observed by the following trains.

The electric block signals on the Harlem road divide that time in sections of one mile each, and not more than one train will be allowed in a section at the same time. The engineer running the last train, can always tell if the forward train is less than a mile in advance of him, and if he finds that such is the case, he is obliged to stop until the signal shows him that the train has passed the next mile-post.

THE CALLAUD BATTERY.

The Callaud battery is composed of a zinc plate in a solution of sulphate of zinc, and a copper plate in a solution of sulphate of copper. By the chemical action there is a constant increase in this amount of sulphate of zinc in solution, and a constant deposit of pure copper. The zinc and the sulphate of copper are consumed.

So far, therefore, as the metals and solutions are concerned, the Callaud battery is identical with the Daniell. The difference between the two consists in the arrangement of the various parts, so as to insure in the former greater constancy with less expense for labor and material than in the latter.

In Callaud's battery, the porous cup is dispensed with, and the solution of sulphate of copper, being heavier than that of sulphate of sinc, remains in the bottom of the jar. In this the copper plate is placed, resting on the bottom of the jar, while the zinc is suspended about 4 inches higher in the solution of sulphate of zinc. Mr. Callaud has made his zincs and coppers in various shapes, but the best results are attained by the arrangement shown in the accompanying diagram. The zinc is a wheel with spokes radiating from the centre with a projection upward from the centre terminating in a wire from which the zinc is suspended at the proper height in the jar. The copper is in the shape of a cross or a star, from which an insulated wire is brought up through the liquid to the next binding post.

Lumps of sulphate of copper are dropped into the jar from time to time, which fall through the zinc to the bottom of the jar. Enough should be supplied to keep the blue color as high as the top of the copper. But the color should never reach as high as the zinc.

The separation of the two solutions as above described, by their difference in specific gravity, is much more perfect than by a porous cup. Local action is thus prevented, and all the material consumed is utilized.

The Daniell battery is itself among the most economical batteries ever used, yet experience on a large scale shows a considerable saving in material by using the Callaud, from the fact that local action is prevented. This saving is particularly manifest in cases where the current is open a part of the time.

But the saving of material variously estimated at 25 to 50 per cent is unimportant compared with that of labor in maintenance, and compared with the advantage of an even constant current.

This longer duration or greater constancy on account of the avoidance of local action, and in consequence of the greater quantity of water for the sulphate of zinc solution, requiring a longer time to become saturated.

Instances are frequent where a local battery has lasted eight to twelve months, until the zinc was entirely consumed, without being taken down, the labor of maintenance being the dropping in of sulphate of copper as before mentioned, and the drawing out of the sulphate of zinc solution and replacing with clear water.

The Callaud Battery is furnished in two sizes, the jars being eight inches high, and respectively five and six inches in diameter. The larger size is used for both main and locals, the smaller for mains exclusively. The resistance of each of the larger sized cells is about two and a half to three and a half ohms. That of the smaller size is from three to five ohms. The electro-motive force is equal to the Daniell and about three-fifths of that of the Grove cup, when they are first set up. That of the Grove or Daniell declines more rapidly than the Callaud.

In another article we will give statistics showing the results of various experience with the Callaud Battery in actual use.

By a dispatch to Mr. Field, dated November 22d, we learn that Australia is now connected with the great Indian lines of communication, by the successful laying of a first-class cable, by the Cable Maintenance Co., of London, between Batavia, on the southern extremity of the island of Sumatra, Southern China, and Port Darwin, Australia. This gives communication, of course, with Melbourne, and the whole line of internal telegraphs on the island, as well as with Hobartown, Tasmania, and to New Zealand. There remains thereafter one grand work to accomplish. A cable from the Australian coast to the Sandwich Islands, by way of New Caledonia and the Fejee Islands, 4,560 miles, and another, of 2,093 miles, from Honolulu to San Francisco, will complete the circle of the globe. American interests, so largely affected by the means of communication, will, at no distant day, demand their being laid.

GOVERNMENT AID TO SCIENCE.

When we look over the long list of benefits which science has conferred on many departments of human industry, and remember that by just so much as these have been bettered has the condition of the people been improved, there no longer remains a question as to the duty of governments toward the cause of science and its promoters. If its paramount object be the welfare of the citizen, and the general diffusion of scientific knowledge, and a liberal encouragement of scientific research will largely add to this, it certainly comes within the province of the Government to see that these are secured. Scientific men as a rule are poor; the practical results of their work are oftentimes remote, and even if immediate are rarely secured by those most entitled to them. Thus it frequently happens that while ready and anxious to give their energies to the advancement of science, they are hindered in their work by pecuniary embarrassment, and are not rarely forced to abandon a field which by their tastes and knowledge they are eminently fitted to cultivate. The services of these working men of science can ill be spared, for in the direction they would take us lies the modern road to national advancement. Germany long ago saw this, and set to work in the right direction. We are told by Sir William Thomson in his recent address before the British Association that in Prussia every university, every polytechnical academy, every industrial school, most of the grammar schools, in a word nearly all the schools superior in rank to the elementary school of the common people, are supplied with chemical laboratories, and a collection of philosophical instruments and apparatus, access to which is most liberally granted by the directors of those schools or the teachers of the respective disciplines to any person qualified for scientific experiments. In consequence there will scarcely be found a town of five thousand inhabitants but offers the possibility of scientific explorations at no other cost than reimbursement of the expense for the materials wasted in the experiments. Professors, preceptors, and teachers of secondary schools are engaged on account of their skillfulness in teaching; but professors of universities are never engaged unless they have already proved by their own investigations that they are to be relied upon for the advancement of science. Therefore every shilling spent for instruction in universities is at the same time profitable to the advancement of science.

This is the relation which Germany takes to science and scientific men; and the position of that country to-day, not only as the greatest military power on earth, but what is a far higher title, "the foremost in science of all the nations," attests the wisdom of the measures which her rulers were the first to inaugurate. England is also rapidly waking up to the importance of the question, and, in spite of the bigoted opposition of the universities and the clergy, has already made great headway in the cause of scientific education; and now her scientific men are demanding of the Government such a liberal cooperation in their work as shall relieve it of the uncertainties of private enterprise, and give it an impulse in some degree commensurate with its importance.—*Galaxy.*

We regret that in the last issue of the JOURNAL our remarks relative to the death of Christopher Reynolds led to wrong impressions, and were not strictly correct. We are happy to state that his last days were spent in comfort, with every want supplied, and surrounded by those most dear to him. The knowledge of this will be a happy relief to his many friends.

A SINGULAR WELL.

The frozen well at Brandon, Vt., has recently been the subject of a report by a Committee of the Boston Society of Natural History. Twelve years ago attention was directed toward this curious well, which remains frozen throughout the Summer months, and a committee was appointed, which continued each year for six years, to visit and examine the well and the surrounding country. A report was then made and published, but, in consequence of the predictions of an eminent man of science, that the ice would soon cease to form in the Brandon well, it became necessary to wait a few years to collect further facts. The committee now reports that for twelve years the ice has remained in the Brandon well, during the hot months of Summer, notwithstanding openings were made in the soil, and a tunnel was run into the gravel bed to give more free access to the warm surface water.

It has been suggested that the water dissolved something from the rocks that makes a freezing mixture, but a chemical analysis shows that one wine gallon of this fluid contains 25.2 grains of solid matter, resolvable into 6.8 grains of vegetable matter, and 18.4 grains of mineral salts. Of the solid matter 2.8 grains were found to be composed of bi-carbonate of lime, magnesia and iron, and sulphate of soda, with traces of chloride of calcium and sodium. There is, therefore, nothing in the composition of the water which will explain the freezing. Other persons, arguing from the theory that electricity produces hail, have assigned the action of the same influence as the cause of the frozen well.

Repeated tests with the magnetic needle failed to disclose any difference in local variation, thus showing that no perceptible electric current was passing through the well or surrounding soil. The original explanation is, therefore, adhered to by the committee. The gravel bed, it is believed, was frozen by the cold of previous rigorous Winters, and the wave of Summer heat has not yet been able to overcome that cold. Brandon is situated in Rutland county, Vermont, and has the same latitude as the Northern part of Lake George.—*Roch. Express.*

THE GLOBE ENGIRDLED.

In the history of applied science there is nothing more marvellous than the development of Telegraphy. Whether it be by overhead or subterranean land lines, or by submarine cables; whether we regard the manufacture of the conducting wires or the invention of instruments for transmitting and recording messages; it is surprising to reflect upon the giant strides that have been taken since the first submarine cable was laid across the English Channel, some twenty or five-and-twenty years ago.

It is within a generation that Telegraphy has risen into note as a special science and profession, and at last received due recognition by the establishment of a Society of Telegraph Engineers.

At the present moment, all that is needed actually to complete a "girdle round the globe," such as Shakespeare only dreamt of, is the connection of the American Pacific Coast and the Islands of Japan; which link in the circumterranean commuuication is now in contemplation. Mr. Cyrus Field has projected a line from Victoria, the capital of Vancouver's Island, to Hakodadi, in Japan, and from thence to the Russian naval station on the coast of Asia, whence, across the steppes of Siberia, the telegraphic wire penetrates to St. Petersburg, and is united with the European system. This new line, the estimated length of which is 4,370 nautical miles, will touch at Atcha, one of the Alcutian Islands. A second route projected is identical with the first, as far as Atcha; it pursues a more southerly course to Yokohama—a distance from the United States of 4,235 miles. From Yokohama it describes a segment of a circle to Shanghai—a further distance of 1,010 miles. A branch crosses the Island of Niphon and the Japan Sea, and joins the Russian lines at Possiette. A third and last route starts from San Francisco, traverses the North Pacific to Honolulu, in the Sandwich Islands, connects this group with Midway Island, and thence to Yokohama—a total distance of 5,573 miles. Making an allowance of 20 per cent. for slack, the length of cable required for the first route is 5,244 miles; for the second, 5,244; for the third, 8,463. Each line is supposed to terminate at Possiette, which is 1,480 miles from Yokohama. It is in contemplation to lay a Cable between Honolulu and the Australian Colonies, thereby establishing direct intercourse between Melbourne and San Francisco. This line is thus divided: San Francisco to Honolulu, 2,093 nautical miles; Honolulu to Fiji Islands, 2,950; Fiji to New Caledonia, 810; New Caledonia to Brisbane, 800—6,653; add 20 per cent. for slack, 1,331; length of cable, 7,984 nautical miles. Brisbane is already connected by land lines with Sydney, Melbourne and Adelaide; also with Port Darwin on the north coast. The Dutch colony is now in direct relation with the India and Chinese cables.—*Mechanics' Magazine.*

TURNING A GALVANIC BATTERY INTO A DETECTIVE.

Many years ago Major Stone, of the Fifteenth British Huzzars, then stationed in India, had a gold watch and chain stolen from his drawing-room table. Collecting all of the native servants of whom he had any suspicion, together, and made them join hands, he told them that presently his God would give them a shock, which, however, would be harmless to all but the culprit; but that, if he was among them, he would, in an hour, turn green and silently die. The black fellows grinned incredulously, when the wires of a very powerful battery, prepared and concealed under the table, were brought in contact with the two end men. So severe was the shock that three of them fell to the ground. The Major then remarked that if the guilty one came to him within a half hour he would give him an antidote that would save his life. The effect of the shock upon the imagination of the superstitious thief was so great as to induce belief in the prospect of turning green and dying, and he shortly came, watch and chain in hand, to beg for mercy and the antidote.

Recently, a similar attempt by a policeman in India, to bring a woman to confessional, was not so satisfactory. The woman died through fright, and the policeman was brought to answer a charge of homicide.—*Roch. Express.*

THE LINE TO MEXICO.

BROWNSVILLE, TEXAS, Nov. 16, 1871.

James D. Reid, New York:

I congratulate you on the conclusion of the line to connect with Mexico. JACOB CAMPBELL.

We believe the public is greatly indebted for the enterprise shown by Mexico to the energy and perseverance and excellent character of our old friend Campbell. He has, practically, the whole work of Mexican telegraph extensions in his hands, and he never yet abused a trust.

We have also the following:

LOUISVILLE, KY., Nov. 15.

Hon. William Orton:

Line completed to Brownsville, Texas, yesterday. Mexican lines are working as far as Mier. The only interruption beyond that point is caused by the revolutionists.

J. VAN HORNE, Gen. Supt.

PROGRESS OF RAILROADS.

A company has been formed in St. Louis, with a capital of $2,000,000, A. L. Green, President, with a directory largely in Chicago and New York, the chief purpose of which is to construct two railroads—one from St. Louis to Arkansas River, 400 miles long; the other from Centralia, Ill., to Wichita, Kansas, 500 miles long.

The Burlington, Cedar Rapids & Minnesota Railroad is completed to Nova Springs, Iowa.

The Davenport & St. Paul Railroad is completed to Wyoming, Iowa, and will be in operation to Monticello, about 75 miles northwest of Davenport, during the month.

The Sioux City & St. Paul Railroad is now complete to Worthington, Minn., 60 miles southwest of St. James.

The Decatur, Sullivan & Mattoon Railroad is nearly complete.

The Baltimore & Ohio Railroad Co. has projected a new route from Pittsburgh to Chicago.

A railroad is projected from McCarmillsville, Muskingum River, 70 miles, to Dennison, on the Panhandle line.

The Detroit, Lansing & Lake Michigan Railroad is in operation to Howard City, on the Grand Rapids Indiana Railroad.

Work has been commenced on the Griffin & Madison (Ga.) Railroad.

The Lafayette, Bloomington & Mississippi Railroad is fast approaching completion.

The Kentucky Railroad, connecting Elizabethtown and Paducah, has been completed 110 miles, and will be opened throughout in July, 1872.

The Denver & Rio Grande Railroad will be completed March 1, 1872, from Colorado Springs to Arkansas River.

A telegraph line has been completed along the Northern Pacific Railroad from Duluth to the Cheyenne crossing, 60 miles west of Moorhead, and from Moorhead to Pembina. It is now also complete to Fort Garry.

The Chicago, Dubuque & Minnesota Railroad is now completed to McGregor.

Toledo is the focus of fifteen railroads. There are now in progress to that city, the following :

Lake Shore road to Elyria, O.	84 miles
Toledo to Mansfield, via Tiffin, O.	88 "
To Pomeroy, Ohio River, connecting with the Chesapeake and Ohio R. R. to Norfolk	225 "
To Holly, to connect with Saginaw line	90 "

These will be opened within a short period.

PROJECTED AND PROBABLE EXTENSIONS.

Toledo direct to Ann Arbor and Owosso, Mich.	135 miles
Toledo and St. Louis Air Line, via Kokomo,	420 "
West Branch Chic. and Canada Southern R. R.	30 "
East Branch Chic. and Canada Southern R. R.	40 "

The photo plate of the Morse Memorial Monograph, as now produced, is a most perfect and beautiful work. The likeness of Prof. Morse in the centre is now executed separately, is fine and clear, and exhibits him with all the medals presented to him by the European governments. The whole measures 12x14, and seems exceedingly cheap. Price $1.25, mailed, post-paid, on rollers. Orders sent to us will reach the publishers, and be promptly filled.

A SINGULAR INQUIRY.

OIL REGIONS, Pa., Nov. 10, 1871.

Editor Journal of the Telegraph :

I have an odd little fellow for Messenger Boy. In this unsettled region of Oil Derricks and territory, scattered over for miles with oil producing interests, it is often very hard work to find parties to whom messages are addressed. A few days ago, we received a message for a certain party ; after looking and inquiring in vain for him, the little fellow astonished me by asking, "If the party whom we were searching for was a Christian." I inquired of him his reason for asking so singular a question. He replied, because he would know better where to look for him. The boy is obliged to go into all sorts of company, at times, to find parties addressed—hence his singular inquiry.

Should you mention this in the papers, you need not give date or place of occurrence, nor my right signature. VICTOR.

OIL CITY, Nov. 13, 1871.

Editor Journal of the Telegraph :

DEAR SIR :—We are using, quite extensively, the Callaud local. Will you be so good as to print in your next issue the proper mode of treatment for them. Please cover the ground fully, so that we may enjoy all its advantages, and avoid the disadvantage of insufficient information. Respectfully.

* * *

OCEAN TELEGRAPHY.

The binding link between all the great questions of taxation, industry and commerce, as well as their adjunct, a sound currency, is ocean telegraphy. Without the telegraph all financial schemes would come to naught. Without ocean cables there can be no revival of American shipping. As it is beginning to be generally felt that the Pacific is to be the great highway of American commerce, and the nations of the East the chief commercial allies of the American people, there are even now three bills before Congress asking for subsidies for submarine cables, to Japan, China, the Sandwich islands, and Australia. These and the subsidies asked for by the proposed American steamship companies, as well as the additional land grants demanded by infantile aud impecunious railroads, are likely to revive the question of giving away money or land for the purpose of promoting the means of land and water communication. The question has two sides, and both will be pretty thoroughly ventilated this winter.—*Herald.*

We learn from a correspondent on the line of one of the Missouri Railroads, that, owing to the frequent intersection of the roads, and the clubbing of offices, communications left for transmission have become almost like public property. So much so is this the case that even the Railroad officials hesitate about leaving confidential dispatches of importance, lest they be read by eyes for whom they are not intended.

Every arrangement which trenches on the sacredness of dispatches should be vigorously opposed. The absence of the means of confidentiality soon impairs the sense of the necessity of their confidential care. The contents of messages thus become a theme of common gossip, and although given in a semi-sacred whisper is none the less endowed with wings and becomes a secret which every body knows. We caution all against this looseness in arranging "joint offices," and trust that the incipient evil may be checked before much further mischief is done. An operator allowing the contents of a message to become known *should* be dismissed without appeal.

ENGRAVING WITH THE SAND BLAST.

The most remarkable invention brought out within the past year is that by Mr. B. C. Tilghman, of Philadelphia, for engraving on glass and stone. By means of a jet of quartz sand, blown through a pipe by steam at a pressure of 300 pounds to the square inch, he can cut a hole in a solid block of corundum—only inferior to the diamond in hardness—in a few minutes. The new process is now exciting great interest in Europe; an English journal thus speaks of it: "This American engineer just turns upon corundum a pipe which discharges sifted sand, mixed with a furious squirting of steam, and the fine shower of particles thus flung cuts a hole equal to the diameter of the jet. The same effect is produced in anything else submitted to the process. Here has the world been grinding, hammering, chiseling, and whirling drills for centuries, to make holes and channels in obdurate substances, when suddenly the friend of our youth, the squirt—in a new form, no doubt—comes to the rescue; and for the future we shall see the work done by this irresistible jet of dust beating in ten million millions of fairy raps upon the object; thus effecting what is wished in a tenth of the previous time, and with exquisite precision. It may be added that the latest adaptation of this new invention is to a peculiar process of replacing the art of wood engraving. It consists in bringing upon a suitable matrix a photographic copy of the drawing or engraving to be reproduced. This is then passed beneath the sand-blast, and the cutting is thus obtained. The reverse engraving is then subjected to the electrotype process, and any desired number of copies are produced."

We have declined few manuscripts sent to us, and these have been chiefly of the poetic character. Writing poetry is a poor business to most people, and making poetry out of signals is desperate. One or two good specimens we published, but these brought down upon us such an avalanche of "call" angels that we had to shut the door.

We must decline "Sorrow's Complaint," by a "retchid plug." We don't see the sorrow, and cannot feel the force of the refrain.

We must also decline the "Lectures by A Fool, No. 1." The subject is not within the liberties of our columns, although written by an intelligent and excellent manager.

A GENTLEMAN of a slightly irritable temper, calling out loudly for some hot water from his bed-room, was unanswered. Seizing a small bureau, he shoved it before him to the head of the stairs, and sent it whirling, end over end, to the hall below. The crash was loud enough to bring out mother, daughter, and all the servants. The head of the family was seated at the head of the stairs, elbows on knees, chin resting in hands.

"Oh, father! what is the matter?" asked the frightened daughter.

"Matter!" said the old man; "why, here I have been a callin' and callin' for very nigh on half an hour, and now I've *telegraphed* for yer, that's all."

THE Swiss Federal Council has sanctioned the International Telegraph Convention, recently concluded, relative to the increase of the telegraph charges on all the Anglo-Indian lines to £4 10s. per 20 words.

TRINIDAD advices state that the telegraphic cable to Georgetown, Demerara, has been laid, but communication is not open, as about 100 yards of land line require to be put upon the south coast to complete the connection, and this, for some unexplained reason, has not been done, though the shore end of the cable was landed several days ago.

THE latest news from Australia states that everything connected with the Overland Telegraph was making satisfactory progress.

Mr. Arthur Cole has resigned his position as Supt. of Telegraph on the Kansas City, St. Joseph & Council Bluffs Railroad, on account of his health, which was rapidly failing. He has gone South, by advice of his physician, and is now in Mississippi.

Mr. J. McConniff succeeds Mr. Cole as superintendent of the above-mentioned railroad lines.

ANSWERS TO CORRESPONDENTS.

Here is a point in reference to checking business which does not seem to be provided for in our present system, whereof we require instructions. It is as follows:

Somerset, Pa., sends a message to Baxter, checked 14 paid. Baxter, unable to find the party addressed, notifies Somerset and is directed to forward message to Kansas City, which is done, dated as per order, Somerset, Pa., via Baxter, and checked 14, collect. Kansas City understanding, of course, he is to collect the rate from Baxter.

Had the message been checked collect from Somerset to Baxter and then forwarded. It being checked "14, collect," as before, Kansas City naturally collected the rate from Baxter only, as in first instance, the result being Kansas City is overchecked by Baxter, who clears himself by returning a copy of forwarded message as cash. But how does Kansas City balance his error sheet, or where does the Company get their pay from Somerset to Baxter? Per rule there should be no amount stated in check, and though Baxter could protect Kansas City with an office message, it is irregular, and is not always thought of.

ANSWER.

When a message is received collect at an office on our line, and is subsequently forwarded collect, to another office on our line, the Manager of the forwarding office should check himself with the tariff from the sending station to his office. He should then check the office to which the message is forwarded for "this line" the tariff from his office to its destination, and for "other lines" the tariff from the sending office to his office, stating both amounts, as provided for by Rule 9. He thus obtains credit as "paid other lines" for the amount with which he first checked himself.

In the case given, where Baxter receives a collect message of 14 words from Somerset, which he forwards to Kansas City, all three points on our lines, Baxter should check himself $2.20, the tariff from Somerset to Baxter, and should check Kansas City 66 cents for "this line" and $2.20 cents for "other lines;" 66 cents being the tariff from Baxter to Kansas City. By checking Kansas City $2.20 for "other lines," Baxter receives credit for the amount with which he has checked himself with Somerset. The forwarded message should be checked: "14, collect 66 and $2.20," and should be dated "Somerset, via Baxter.

KANSAS PACIFIC RAILWAY,
Hays City, Ks., Station,
Nov. 10, 1871.

Editor Journal of the Telegraph:

DEAR SIR: Leavenworth, Kansas, is over 250 miles airline from me. I send him a message of 22 words, Government rates. Please give the amount of check, *per Ex. Order No.* 125. Does the part of the order that reads, "That no message shall be computed as less than *twenty-five* words," apply to messages where the tariff is at least 25 cents? GOVERNMENT RATE.

ANSWER.

Ex. Order No. 125, in relation to Government messages, must be construed exactly as it reads, viz.: "No message shall be counted as less than twenty-five words." All messages, therefore, of less than twenty-five words must be charged for as if containing twenty-five words. The tariff on a Government message of twenty-two words from Hays City, Kansas, to Leavenworth, distance over 250 miles, two circuits, is 50 cents.

INDIANAPOLIS, Nov. 23d, 1871.

To the Editor of the Journal of the Telegraph:

Please publish an answer to the following question: When we receive a message from another company for transmission to its destination by our lines, do we charge for three extra words in date up to twentieth, and four extra from that to thirtieth, or do we charge them for all they write before our date? For instance, we receive a message dated Hamilton, O., Nov. 23, how many words are we to charge for that date? Again, New York, 10th, via Indianapolis, &c., what are we to count? The example in Book of Rules may hardly be said to explain it fully, and we have had some controversy about it here.

M. D. BUTLER, Manager.

ANSWER.

"Hamilton, O., Nov. 23d," should be charged for as FIVE extra words. The rule is to charge the other Company for all they write before our date; *not less than three words*, to be charged for in any case. "Twenty-first," "twenty-second" &c, are each two words.

INTERPRETING RULES.

There can scarcely be a rule devised so broad or clear that some exception to it may not be found in its practical operation, and which, under some circumstances, may work injuriously. In such cases, the facts appeal to the judgment of the manager and test his ability. The following question is, perhaps, one of these:

"Suppose a party to inquire, during the evening, for a message, and at the time propose to pay the additional half rate on any "Red" message for him that might be waiting the usual time for delivery. Can it be delivered to him?"

Now it seems very arbitrary to answer NO; yet it is the only one which can be given. "Red" messages are a distinct service which contemplates a morning delivery, and if it has its disadvantages to the party addressed, to relax the rule would be to place messages under the operation of two systems, and lead to evil. To such looseness there could be no check.

At the same time there may sometimes occur some peculiar combination of circumstances, some peculiar danger, or some emergency which would justify a manager to deviate from the rule. The answer, however, remains, NO.

ANOTHER.

"Can a 'Red' message be delivered, under ordinary circumstances, the same night it is received, provided the party is willing to pay the additional half of the tariff?"

Answer.—No.

A LADY'S INQUIRIES.

NOVEMBER 13, 1871.

Editor Journal of the Telegraph:

DEAR SIR: Will you be so kind as to answer a few questions, if not too much trouble to you? 1st. Is there much demand for lady operators; and can a lady secure a good situation more easily by going to the Cooper School of Telegraphy and graduating? 2d. Who would be the proper person to apply to for admission to that Institute? 3d. How long do you think it would be necessary for a person to practice, to become a ready receiver by *sound*, who is already an operator of some experience in all else pertaining to a small office, and can read a very little by sound?

Will you please answer in the next number of the JOURNAL, and greatly oblige A LADY OPERATOR.

ANSWER.

1. Opportunities for employment are constantly occurring, and the evidence of ability shown at the Cooper School is undoubtedly an advantage.

2. Miss Lizzie H. Snow, Manager Ladies' Department, 145 Broadway, New York.

3. That depends. If your ear is good, with your present attainments, three to six months' faithful practice should qualify you.

The *Chicago Railway Gazette* has been from its first number a prince among American Journals, esteemed as it deserves at home, and valued by the highest scientific Journals abroad. No better proof of its energetic management could be shown than the fact that, though its whole material and offices were destroyed by the great fire, the *Gazette* has come along undiminished by a single number or line. We greatly regret our tardy acknowledgement of it.

THE FIRST IDEA OF A DIAL TELEGRAPH.

Dr. Quesneville, the author, quotes a few curious lines, taken from a work—"Récréation Mathématicque Composée de Plusieurs Problèmes Plaisantes et Facétieux," edited by Jean Leurechon, e S. J., Anno 1624, at Pont-a-Mousson—the main gist of which is that the *savant* just named, while speaking of the magnet (loadstone), suggests that if a person, A, had a powerful stone at Paris, and was provided with a dial plate, upon which the figures of the alphabet were engraved, and to which a movable magnetized needle was adapted, and a person, B, being at Rome, was provided with a similar apparatus, these parties might, by previously agreeing to enter into conversation with each other at a certain hour of the day, so arrange as to be able, by the aid of a strong magnet, to converse with each other. It appears that there was added to the original text an engraving representing the dial and needles alluded to. The work just spoken of has been republished in 1626 and in 1629 (printed at Rouen by Ch. Osmont). The passage alluded to also occurs in a work edited in 1636 by Wijnant van Westen, a mathematician at Nymegen (Netherlands), under the title "Mathematische Vermaeckelijkheden." This work is an improved Dutch translation of the work of Leurechon, who used to write under the pseudonym of H. van Etten.—*Chemical News.*

TESTIMONIAL TO A WORTHY MAN.

PORTLAND, Nov. 14, 1871.

To J. D. Reid, Esq.:

DEAR SIR: One of the best of operators has just graduated from the Bangor (Me.) office, and gone into mercantile business.

Mr. F. A. H. Pillsbury was one of our finest operators, and by his strict application and fine penmanship contributed greatly to the enviable reputation which our Bangor office hold as a first-class office.

Yours very truly,
J. S. BEDLOW, Supt.

We are glad to publish the above. Mr. Pillsbury was an honor to the craft, and will, we doubt not, honor his new vocation and "organize success."

Now that a time is at hand when the telegraph is required to transmit public documents and statements containing large numeral sums, we would suggest to telegraph operators the propriety of telegraphing these sums fully written out in words. As usually transmitted and copied these statements are a farce. For example, the Associated Press report of Treasurer Spinner's annual report, as printed in all the Cincinnati papers of Wednesday, gave the receipts of the year, including previous balance in the Treasury, as $980,904,349; expenditures, $870,986,872. Nor is this extraordinary, it is about an average specimen of the luck in transmitting large sums.—*Cincinnati Gazette.*

We think the caution well timed. The production in words will secure correctness, and give faith in the statements of public affairs by telegraph.

WORCESTER, Mass, November 20., 1871.

J. D. Reid, Esq.,

DEAR SIR:—In reply to the inquiry from Syracuse of November 9th, I would say that his information is erroneous. The regular force of this office consists of four operators, one of whom is engaged upon night press reports. Of course it could not be expected that this force could transmit the amount of press matter already stated, within the time given; and, also, attend to the largely increased regular business which the Convention would necessarily produce. But two operators were sent from the Boston office to aid us. Our press news was transmitted over six wires equally divided between Boston and New York. It was not my intention to detract a particle from the praise due Syracuse, but I considered the performance worthy a notice in your Journal. Yours Respectfully,

E. W. BRADFORD.

FAMILIAR TELEGRAPH TALKS.

In attempting to continue our talk on the best mode of learning the alphabet, we referred to Pope's Manual to see what he had said on the same subject. After reading it over, although it occured to us that his teaching was rather solemn and his cautions somewhat abundant, yet it was perhaps superior to what we could ourselves provide, and we, therefore, copy from that excellent work:

HINTS TO LEARNERS.

In the excellent little manual of Prof. Smith, six elementary principles are laid down as the basis for practicing the alphabet, viz:

First principle. Dots close together.

I S H P 6

Second principle. Dashes close together.

M 5 ¶

Third principle. Lone dots.

E

Fourth principle. Lone dashes.

T L or cipher

Fifth principle. A dot followed by a dash.

A

Sixth principle. A dash followed by a dot.

N

The student may now proceed to practice upon the elementary principles.

1. Practice making *dots* at regular intervals, until they are produced with the regularity of clock-work, and of definite and uniform dimensions. The regular tick of a watch or of a short pendulum is a valuable auxiliary in acquiring this habit.

2. Next proceed to make dashes, first at the rate of about one per second of time, which may afterwards be slowly increased to three. The space between the dashes must be made as short as possible. If the upward motion of the hand, in forming the space, be made *full*, it cannot be made too quick,

3. The third principle occurs but once in the alphabet, and forms the letter E. It is made by a quick but firm downward movement of the key. In practicing upon this or any other character, it should not be repeated too rapidly, nor should the thumb and fingers be taken from the key in the intervals between the successive repetitions of the letter.

4. The fourth principle is somewhat difficult. The usual tendency is to make T too long and L too short It will be observed that the same character is used for L and the cipher or 0. Occurring by itself or among letters it is always translated as L, but when found among figures becomes 0. This would at first seem liable to cause confusion, but in practice it is found not to be the case. It was formerly the custom to make the cipher equal to three short dashes.

5. The fifth principle, which forms the letter A, may be timed by the pronunciation of the word *again*, strongly accenting the second syllable. The tendency of beginners is usually to make the dot too long and the dash too short, and more especially to separate them too much.

6. The final principle, the dash followed by a dot, usually presents some difficulties. The univers l tendency of the student is to separate the dot from the dash by too great a space. Time the movement by pronouncing the word *ninety*, with the first syllable somewhat longer than usual.

Having become thoroughly conversant with the six elementary principles, the following exercises may be taken up in order:

(1.) E I S H P 6

These should be practiced separately, until the right number of dots can be made invariably, the last dot in each being neither shorter nor longer than the preceding ones.

(2.) T M 5 L or cipher.

In practicing this exercise, care must be taken not to separate the dashes too much, and to make the final one in each letter exactly equal to the preceding ones. Observe not to make the M too short. There is a general tendency in beginners to shorten the final dash, where two or more occur together.

(3.) A U V 4

The usual tendency to make too much space between the dot and dash in the above letters, may be avoided by making them as if by prolonging the final dot in I, S, H and P.

(4.) I A S U

H V P 4

These are to be practiced in couples, as represented, the object being to impress upon the student the difference in the characters thus coupled together.

(5.) N D B 8

The student having thoroughly mastered the sixth elementary principle, he will have no difficulty in forming the above characters.

(6.) A F X Parenthesis

Comma Semicolon W 1

The only caution necessary in this exercise is to form the letters compactly, with the dashes of equal length. (See Exercise 2.) Observe, that the Parenthesis may be formed by running A U together, and the Semicolon by A F, etc.

(7.) U Q 2 Period 3

These differ but little from exercises previously practiced, and require no particular directions.

(8.) K J 9 Interrogation

G 7 Exclamation

J and K are generally considered the most difficult letters in the alphabet. Do not separate J into double N, and be careful that the dashes correspond in length. (See Exercise 2.) The figures 7 and 9 require care in spacing correctly.

(9.) O R & C Z Y

These are termed the "spaced letters," and require great care in order to make them correctly. The "space" should be just double that ordinarily used between the elements of a letter. The usual tendency is to make it too great. It should be just sufficient to distinguish these characters from I, S and H.

If the principles laid down in this work be firmly adhered to, the learner will be surprised, not only at the rapidity with which he masters what appears to be a very difficult lesson, but at the extreme accuracy with which he manipulates his instrument. He must also carefully bear in mind that one of the most universal faults, among those attempting to learn the telegraph art, is that of going over a great deal and learning nothing well.

READING BY SOUND.

This can only be attained by constant and persevering practice, keeping in mind the principles above given. The lever of the Morse apparatus makes a sound at each movement, the downward motion producing the heavier one, or that representing dots and dashes; or, more properly, the heavy stroke indicates the commencement of a dot or dash and the lighter one its cessation. A dot makes as much noise as a dash, the only difference being in the length of time between the two sounds. Thus, if the recoil or lighter stroke be dispensed with, it would be impossible to distinguish E, T and L from each other.

In learning to read by sound it is best for two persons to practice together, taking turns at reading or writing, and each correcting the faults of the other. The characters must first be learned separately, and then short words chosen and written very distinctly and well spaced, the speed of manipulation being gradually increased as the student becomes more proficient in reading. After becoming sufficiently well versed in the art to read at the rate of twenty-five or thirty words per minute, the best practice will be found in copying with a pen and ink from an instr - ment connected with a line employed in transmitting regular commercial messages, in order that the student may familiarize himself with the usages of the lines and the minute details of actual telegraphic business.

In conclusion, the student is warned against falling into the common error of expecting great results from little labor. To become an expert operator requires much time and patience, and the most unwearied application. Remember, that whatever is worth doing at all is worth doing well. The time will seldom or never be found when a thoroughly competent operator cannot obtain immediate and remunerative employment, however overcrowded the lower walks of the profession may have become.

MAGNETISM AND THE SUN.

What the wonderful immaterial agency may be by which matter in its free, elemental, metallic state influences and attracts other metallic matter at a distance, or by which the earth acting upon a balanced steel needles causes it to point to the pole, we are far enough from knowing; but whatever it be, it belongs to the solar system and involves the sun in its effects. It has been known for some years that the magnetic needle is in sympathy with the solar spots; that is, they each have eleven-year periodicities which coincide with each other. Great perturbations of the solar surface—cyclones in the sun's atmosphere—it is also known, are attended with agitations of the needle over large areas of the earth, which take the name of magnetic storms. It is a very natural supposition, therefore, that so grand an obstruction to solar influences as a total eclipse of the sun would result in some form of magnetic derangement on the earth, and this is the case to so important an extent that magnetic observations are now extensively provided for. Mr. Diamilla Müller records in the "*Gazette Official del Regno d' Etalia*," that on the 22d of December last, the needle followed its usual course until the commencement of the eclipse; then it went backward until 1:58 a. m., when it attained its maximum declination at the time the eclipse became total. Afterwards it resumed its movement westward, until it exactly took up the position occupied before the commencement of the eclipse.—*Galaxy*.

F. C. Gay, well known by New York operators, and who has more recently been in charge of the telegraph and express business in Wallace, Kansas, has just been elected to the Kansas Legislature by a very decisive vote. He is a man of undoubted probity of character, and we rejoice in his elevation.

The suit of *Hummaston vs. The American Telegraph Co.*, to compel payment of a contract to purchase, under certain conditions, certain machinery for punching paper, and for automatic transmission, has been before the courts for the past ten days, and has not yet terminated. The testimony involves the merits of the automatic processes, but we have no room to do more than thus briefly allude to the suit.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JAMES D. REID, Editor,

Executive Rooms, Western Union Tel. Co.,

145 Broadway, New York.

NEW YORK, DECEMBER 1, 1871.

VOLUME V.

The close of our Fourth Volume was marked by the day of National Thanksgiving. It was an appropriate ending into which we fully entered, not to particularize all which, on that day of turkey and cranberries, entered us. We hope all our readers were as happy, and not less grateful.

"When gratitude o'erflows the swelling heart
And breathes in free and uncorrupted praise,
For benefits received; propitious Heaven
Takes such acknowledgement as fragrant incense,
And doubles all its blessings."

Now we enter our fifth volume. We begin it with a glimmer of comfort from our past work. We are assured it has not been fruitless. The testimony comes from hands we never saw, but represent names honored and successful. We accept it as an encouragement. The year will be one of increased success, if the fulfillment of our desires bears any proportion to their present extent. The work of instruction has scarcely begun. We have much to learn, and therefore much to communicate. We shall be assiduous to acquire, and free to give.

The past year has been one of wondrous progress. It has seen the ends of the earth reached. Japan, Mexico, Australia now shake hands with wire-webbed Europe and America. The diplomacy of the world is now conducted largely by telegraph, the wires reaching and entering every court where civilization has erected intelligent authority. Nearly twenty thousand miles of cable has been added to the means of sub-oceanic communication, in addition to at least one hundred thousand miles more of land wires in all parts of the earth. Only one ocean now waits the living ligament which shall make the orient and the occident one. The girdle will then be complete. We expect to see its completion and join in its jubilee.

Now comes a greater work. The telegraph has to be made a companion, a part of home, an eye to commerce in all its minor details, giving ubiquity to authority, and prescience to power. A vast development of its capacity in its local uses has already been made, and the history of which we are soon to give. Its employment on railroads is entering new phases, and will prove their grand guardian and guide. On one or two roads the sweeping trains already mark their transit in front and in rear, so as to command undisturbed possession of the track and secure immunity from danger. In Europe this is already becoming common. This power the wire gives them. It will do much more some coming day. The science of the century seems brooding with its calm brow over the possible limits of the realm which electricity, occult, subtle, mysterious, omnipresent, is to reach, and over which it is to reign.

INTERNATIONAL OCEAN TELEGRAPH CO.

A printed statement, issued by the International Ocean Telegraph Co., makes the following exhibit of its affairs:

1870.	
Receipts from all sources, . .	$264,283 80
Expenses, ...	153,837 54
Profit 1870, ...	$110,446 26
1871.	
Receipts from all sources, .	$214,278 77
Expenses, ...	140,607 32
	$73,671 45
Add payments made on account of previous years, ...	$13,565 48
Actual Profit of 1871, . .	$87,236 93

The estimated loss to the company, caused by the interruption to the cable between Punta Rasa and Key West, is stated at $49,000.

Allowing the payments on accounts of former years and adding the estimated losses referred to, the two years would stand in the following relation to each other:

1870, Profits, ...	$110,446 26
1871, "	136,236 93
COMPARISON IN STERLING.	
Actual earnings, 1870, ...	£20,453
Actual earnings, 1871, ...	13,642
1871, with allowances added, . . .	25,229
CURRENCY INDEBTEDNESS.	
Bonds unpaid, ...	$125,800
Scrip issued and unredeemed, . .	117,084
	$242,884
CAPITAL.	
Common stock, ...	$850,000
Preferred, ...	650,000
	$1,500,000

The statement, notwithstanding the special disasters of the year, which are exceptional, and may not occur again for some time, show a healthy business and a valuable stock.

The suit of *Hummaston vs. The American Telegraph Company*, which has been before the courts in New York during the last ten days, and which called together a number of telegraph experts, was closed on the 29th, by a verdict for the plaintiff, of $7,500. The suit involved the value of the automatic processes to which we may again refer.

THE LECLANCHE BATTERY.

LONDON, 11th Nov., 1871.

The Editor Journal of the Telegraph.

Sir:—In number 95 of the JOURNAL OF THE TELEGRAPH, I observe a mistaken statement with regard to the Leclanché or peroxide of *Manganese* battery, copied from the London *Chemical News*, and to the effect that these batteries at the Post Office have to be removed after an hour's work.

It is true that this battery does not answer for a local, but it is of the very greatest service for a line, especially at stations where there is but little business, for at such a station it will last for nine or twelve months without attention, if the connections be well varnished, and if evaporation be prevented.

In the British Postal Telegraph Service we have many thousand cells, a very small proportion has at present been worn out or replaced; but we have never used them as locals.

It is right to add that the writer of the article you produce, has corrected his statement in the *Chemical News*, Oct. 6th.

I need not say that we do not use constant currents on your plan, but work by *making* instead of by *breaking* the battery circuit, so that our battery is in use only when signals are being transmitted.

I am, Sir, yours faithfully,

R. S. CULLEY,

Chief Engineer Postal Telegraphs.

We read an article not long since narrating how a repairer, having been sent out to remove an obstruction on the line, claimed to have found the trouble in the local battery. Of course, he was ridiculed. The local battery being on a circuit of its own, and entirely local, no such obstruction was, of course, deemed possible.

Not so fast. The laugh may be on the other side. Common men sometimes find what scientists fail to discover. The repairer in this case even, may be correct.

It is well known that the burning of the silk on the coils of relays, by lightning, is far from being uncommon. This burning not unfrequently takes place on the convolutions of the silk covered wire nearest the core, so as to bring the core of the magnet in the main circuit. It is equally well known, also, that the armature of the relay is often brought up very close to the faces of the cores, upon fine adjustment, or rather when the current is, from any cause, weak. Under such circumstances, the touch of the armature on the core, is all that is needed to connect the main with the local circuit.

This contact, however, would be harmless were care always taken to have the local battery in a dry place, and carefully tended. Often, however, it is put in damp cellars, often even on their floors. This gives, of course, a good ground connection. It is under such circumstances that an escape through the local connections is easy, and, indeed, frequent. Care in all these matters is essential. The manager of an office should be suspicious of every thing which can in the most minor degree impair the line currents. He may take a hint even from a repairer, and those who have their locals stowed away in damp places should see that a change is immediately made.

STAMP FRANKS.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
New York, November 17, 1871.

Executive Order, No. 133.

INSTRUCTIONS FOR THE USE OF STAMP FRANKS.

The conditions printed on the cover of each of these Franks are as follows:

CONDITIONS.

"This Frank is intended to cover only the personal and private messages of the holder and answers thereto. It is not designed for business or political communications.

"A stamp must be affixed to every message containing twenty words or less, not including address, date or signature, and an additional stamp for every additional twenty words or less.

"If the sender desires to have an answer returned free, he may Frank it by affixing to his message the stamps required under the above rule.

"The holder of this Frank, by accepting and using it, assumes all risks, and agrees that the Telegraph Company shall not be liable for damages, whether from negligence of Agents or from whatever cause arising."

INSTRUCTIONS TO MANAGERS.

The stamps are inclosed in covers, on which are inscribed the name of the person to whom the Frank is issued, and the territorial limits within which it should be used.

Each stamp bears the number of the book inclosing it, and all stamps issued to the same person during the year, will bear the same number.

Receiving Clerks should satisfy themselves, if possible, by inspection of the book, or otherwise, that stamped messages are signed by or addressed to the party to whom the Frank was issued. But they have no discretion to refuse a message when properly stamped, unless they have reason to believe that neither the address nor the signature is that of the Frankholder. A stamp is conclusive, unless there is evidence to the contrary.

It is proper, however, to call the attention of the customer to any violation of the conditions, in respect to territorial limits, or to the business character of the message offered. Gross abuses of privilege should be at once reported to the Superintendent.

Anything in Executive Order, No. 119, conflicting with the above, is hereby revoked.

WILLIAM ORTON, President.

GOVERNMENT MESSAGES.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
New York, November 23, 1871.

Executive Order, No. 134.

The contract entered into between the United States Government and this Company, dated 1st November, 1861, having expired by limitation on the 1st November last, hereafter no government messages will be transmitted free on subsidy account over the Pacific Line from Omaha or Brownsville, Nebraska, to San Francisco.

WILLIAM ORTON, President.

THE ANGLO-AMERICAN CABLES.

So much has been said respecting the purchase by the English Government of the Anglo-American Cables, that, at our request, the following messages have been placed at our disposal:

H. Weaver, Manager, Anglo-American Telegraph Co., London:

Some newspapers here assert that the English Government are negotiating for the purchase of the Atlantic Cables. Is there any foundation for this assertion? Has any person connected with the English Government said anything to you or any Director of the Anglo-American Company on this subject? Please answer fully by telegraph. CYRUS W. FIELD.

Saturday.

C. W. Field, New York:

No such negotiations have been commenced, and, so far as I know, the assertions are entirely void of foundation. WEAVER.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.

Editor Journal of the Telegraph:

In a former issue you criticized the correctness of the following statement of Sir Charles Bright, as published in the Prospectus of the West India and Panama Telegraph Co.:

"Sir C. Bright, who has recently returned from the West Indies, has made a report upon the probable revenue to be derived from the Company's lines. This report, prepared from estimates, based upon *official returns*, and the *actual results of the existing Cuba Line (earning* after 18 months' working at the rate of £60,000 a year) fixes the probable receipts from messages on the Company's lines at £156,000 a year, and the working expenses at £20,000 a year."

I inclose you the official returns of the INTERNATIONAL OCEAN TELEGRAPH COMPANY, for your justification. If the earnings of years, prior to 1870, justified Sir Charles Bright in his statement, all will be pleased to know it. If such prove to approximate £60,000 per annum, it will be the first instance, yet known in the records of any company, free from opposition and under an admirable superintendant, where the earnings have fallen off from 40 to 60 per cent below its former revenues.

I and others object to the statement for several reasons:

1. Because we regard it as evidently and grossly incorrect.

2. Because it was unnecessary.

3. Because it renders every Director of the West India and Panama Telegraph Co., personally liable for all investments made therein. As a proof of this, we present the case of Peek and Overend, Gurney & Co., in London, where the court has just decided that a misstatement of fact in the prospectus would have entitled the investor to recover if his action had been sufficiently prompt. The present seems a time to insist on the strictest regard to truth in telegraph as in all other enterprises. MERCATOR.

Scribner's Monthly is, of its kind, the most acceptable which reaches our table. Its articles are cheerful without being low, and pure without being constrained. It is a magazine which is pre-eminently fitted for the table of an intelligent and refined home.

We begin with this number our "Familiar Telegraph Talks," and hope to keep them up regularly hereafter.

The commencement of a new volume should suggest to all subscribers the duty of sending us a dollar each. We help the suggestion by proposing attention to it.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
December 1, 1871.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since Nov. 15th, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

262	Acton, Ind.	372	Marianna, Ark.
30	Barton Landing, Vt.	397	Milton, Van Buren Co., Iowa
	Brownsville, Texas, tariff,	123	Oakland, Md., re-opened.
	$1.00 more than square,	109	230 Oakleys, Mich.
*	Boseman, Mon.	140	Petersburgh, Clarion Co., Pa.
139	Cassadaga, N. Y.	52	Raritan, N. J.
500	Corsicana, Texas.	260	Richmond, Allegan Co., Mich
228	Camilla, Ga.	139	Sinclairville, N. Y.
437	Edgarton, Mo.	152	Salem, W. Va.
377	Iowa, Ill.	500	Tehuacana, Texas.
39	Leicester Junction, Vt.	41	Westchester, N. Y.
337	Mt. Pulaski, Ill.	337	Warrensburg, Ill.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.	*Leaves this Line.*
Boseman, Mon.	150 10	Helena, Mon.

OFFICES CLOSED.

Cochran, Ga., Eastman, Ga., Hawkinsville, Ga., Lumber City, Ga., and Union, N. Y.

GENERAL INFORMATION.

The name of the office heretofore known as East Sandy Creek N. Y., has been changed to Lacona, N. Y.; that of Coalsmouth, W. Va., changed to St. Albans, W. Va., and Okaw, Ill., changed to Arcola, Ill.

Business for Communipaw, N. J., will hereafter be delivered from Communipaw Stock Yards, N. J. Charges for delivery, 25 cents.

Hereafter, messages for Harrison Square, Mass., will be sent and checked to Boston, Mass., charges for delivery, 50 cents.

Brownsville, Texas, is excepted from the night message "half rate" system.

The P. O. address of Sinclairville, N. Y., is Gerry, Chautauqua Co., N. Y. P. O.

112 Petersburg, Pa., is in Huntingdon Co., Pa.

Elwood, Kansas, new office in last JOURNAL, is in square 446.

The tariff to square 109 is 10 cents more than to square 493.

OFFICES HAVING "SPECIAL SHEET A,"

Will hereafter check Macon, Ga., 25 cents more than "special rate" to Savannah, Ga.

ATLANTIC CABLE BUSINESS.

We are notified that a new route to Japan, via the Great North Western Telegraph Co., through Russia, is now open. Tariff as follows:

From London to Nagasaki:

For 20 words or less, $21.50.

Half the 20 word rate for every additional 10 words or fraction of 10 words.

Messages by this route must be addressed "*via Russia,*" which words *are not charged for* beyond London.

Messages for places in Japan, other than Nagasaki, must be addressed "post Nagasaki," and these words *must be charged for*; but no charge is to be made for postage.

WILLIAM ORTON, President.

As there is but one style of message envelopes for all classes of communications, of course no one is able to discriminate as to the importance of one over another. It thus happens that where a party is in the frequent reception of communications by telegraph, they are all indiscriminately laid upon the desk or table to await his return to business, or his arrival, if absent. Should one of these be respecting death, or extreme danger, it of course remains with the others, and, occasionally, leads to much bitter disappointment. Thus a party leaves his office at 4 p. m. A message arrives at 4:30, and remains until morning. It is easy to appreciate the circumstances of such a case.

A distinguished jurist in an Eastern city, who not long since suffered from this cause, suggests that all messages relating to death be enclosed in a *mourning envelope*, so that instant attention may be given to them, and their urgency be thus indicated. The suggestions which come from actual experience are always worthy of attention.

PRESENTATION.

CAPTAIN WILLIAM MACKINTOSH.

Capt. Mackintosh is, as most people know or should know, foreman of the mechanical work and cable laying of the Western Union Telegraph Company in and around the city of New York. His work is always done well and carefully, and, although usually crowded with imperious demands for many things, all to be executed at once, usually does them, and so preserves the general content. It is comfortable to have him round. His work has been done also without harassing and badgering his men, but, on the contrary, has begotten for him on their part, a respect and deference which has made work on both sides a pleasure. Not only so, but throughout the fraternity he has secured for himself a feeling of respect and friendship, which alone can explain what we have now to narrate.

About 5:30 P. M., Wednesday, Nov. 29, as the captain was busy at his desk, making allright for Thanksgiving, and looking forward as all men with royal stomachs had a right to do, to the turkey and cranberry sauce of the coming day, he was suddenly pounced upon by a large body of men, whose first appearance was apt to convey suggestions of alarm. But it required but a moment to unmask its friendly purposes, and the captain was asked by voices he knew, to face the crowd. Mr. W. K. Applebaugh was thereupon called to preside, who, after requesting Mr. Mackintosh to give the meeting his attention for a moment, called on Mr. John Gough to explain fully the object of the gathering.

Mr. Gough thereupon addressed Capt. Mackintosh, as follows:

"I have been selected by a number of your friends to present to you, on their behalf, the beautiful gold watch I hold in my hand, and to request your acceptance thereof, as a token of the esteem in which they hold you. It is not presented to William Mackintosh, foreman, but to William Mackintosh, the man. Wear it for our sakes, and let it be a perpetual memory to you of the esteem which prompted the gift."

The watch bore the following inscription:

Presented to
WILLIAM MACKINTOSH,
By his Telegraphic Friends.
New York, Nov. 30, 1871.

As soon as Capt. Mackintosh had recovered himself, he feelingly responded somewhat as follows:

My Dear Friends:—You have surprised and embarrassed me. It is difficult for me to understand why I should be the recipient of such a gift. What have I done to cause you to make me such a testimonial? I have done nothing which each of you, my friends, has not as fully done. We have each done our duty, to the best of our ability. We have done it without hope or expectation of any unusual reward. We have done it because it was right and honorable to the great Company we serve, to do our work well and heartily. To what then can I attribute this most unexpected and handsome gift?

Ah! well, friends, it may be unkind in me to be too anxious about the cause of this gift. I take it to be the exponent of that fraternal feeling which is becoming, haply, so characteristic of the telegraphic craft, and which finds, on this occasion, an avenue through me. I ought to be proud of my fellowship with you, my telegraphic friends, as I am grateful for your expression of it to me. And to you, my men, some of whom I see before me, who have served me so faithfully and so well, let me express my heartiest thanks that although in our duties I have to direct and you to serve, yet when our work is done, we are alike friends.

I accept, therefore, your gift, gentlemen, with becoming gratitude and surprise. This golden recorder of time shall, I know, record no time to me, when this night with its gift and cheer, will fade from my memory and my heart.

TELEGRAPHERS' MUTUAL LIFE INSURANCE.

We are pleased to notice the presentation to T. C. James, Esq., Superintendent of Telegraphs on Prince Edward Island, and his new and handsome bride, of a handsome tea service. Pleasant and felicitous addresses were made by the donors and pleased receivers. Mr. James was married to Miss Sophie E., daughter of James G. McKeen, Esq., of Port Hastings, C. B., October 31. Joy be with them.

WANTED,

By a young lady, a situation as telegraph operator, "Sound." Would prefer a place in or west of New York. Address, for two weeks, Miss EMMA E. NORTON, Boston, Mass.

THE LOCAL BATTERY.

We have mentioned two things essential to a local battery, namely:

1. That no more sulphate be placed therein than is necessary for a fair product of sound, and that anything beyond this causes over action, creates deposits which initiate local action within the cell, and which ultimately and speedily destroys the power of the battery, although the material of which it is composed may be largely unconsumed.

2. That the zinc should never, under any circumstances, be allowed to touch the porous cell, the effect of such a contact being practically to ignore the purpose for which it is employed. This is seen in the copper deposits so much complained of on the walls of the porous cell, and which will cease to exhibit themselves, unless the porous cells are very impure, when the zinc is either suspended, or separated from the cup by supporting it on wood or glass. We incline to prefer suspension.

We now mention two additional items:

1. It will be remembered that Mr. Walker stated that he kept his battery in a close box. This is an important item in a constant battery. Its object is simply to prevent evaporation of the water of the cell, and by which the primitive action within is preserved unchanged. Evaporation in warm weather is very rapid, and this is made evident by the frequency with which the cups have to be filled. The reduction of water, of course, increases the proportion of the sulphate, and so by simple evaporation, the battery over acts, as in the case of an over supply of the sulphate. An air tight box in a dry place partially prevents this.

2. A plan extensively used in France is the pouring of a little oil in the liquids to prevent evaporation, which it accomplishes perfectly. It is worth while to try it, if only to see what a curious garden will, in a few weeks, grow upon the oil surface, beginning with the positive cell.

BORN.

On November 22, to B. S. BYNUM, manager W. U. office, at Horn Lake, Mo., a son.

MARRIED.

FULTON—PATTON.—At the residence of the bride's mother, Nov. 14, 1871, by the Rev. Dr. Mophat, Mr. Frank Fulton operator, Gen'l Supt's. office, Kansas & P. R. W., Kansas City, Mo., to Miss Hennie A. Patton, of Wheeling, W. Va.

WAGONER—WILLETT.—At Burlington, Kansas, September 12th, Mr. H. M. Wagoner, of Emporia, Kansas, to Miss Fannie E. Willett, of the former place.

MOORE—MAJOR.—On the 14th ult., at the residence of the bride's father, 1121 Vine street, Philadelphia, Mr. J. Charles C. Moore, of W. U. Continental Hotel office, to Miss Emily J. Major.

MALIN-MILES.—At the residence of Genl. James A. Beaver, Bellefonte, Pa., Thursday, Nov. 23, 1871, by the Rev. N. T. Nylie, Wilmer L. Malin, manager Bellefonte office, to Miss Lizzie H. Miles, of the same place.

JARVIS—COBURN—At the Messenger House, in Cortland, on Wednesday, the 8th day of November, 1871, by the Rev. J. M. Benedict, Mr. Albert J. Jarvis, Manager W. Union Telegraph office, and Miss Ada B. Coburn, both of Cortland.

"Thus hand in hand through life we'll go;
Its checkered paths of joy and woe
With cautious steps we'll tread."

We extend congratulations to the bride, for having secured one of Cortland's nobliest young men, and to the groom for having won to himself, one of her fairest and most accomplished daughters.

DIED.

OSBORNE—At Navasota, on the 10th inst. J. M. Osborne, of pneumonia. He had been for twelve years in the employ of the Western Union Telegraph Company, and up to the time of his death was Telegrapher at Navasota.

One of his companions writing of him from Hempstead, Texas, says: "Joe was one of our very best men, a man, beloved by all on the line and not least by his Superintendent, Mr. Shepherd." He was not a member of the Insurance Association.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 2. NEW YORK, DECEMBER 15, 1871. WHOLE NO. 99.

THE PRESIDENT'S MESSAGE.

THE POST OFFICE AND TELEGRAPH SYSTEM.

The enlarged receipts of the Post Office Department, as shown by the accompanying report of the Postmaster General, exhibits a gratifying increase in that branch of the public service. It is the index of the growth of education and of the prosperity of the people, two elements highly conducive to the vigor and stability of republics. With a vast territory like ours, much of it sparsely populated, but all requiring the services of the mail, it is not at present to be expected that the department can be made self-sustaining; but a gradual approach to this end from year to year is confidently relied on, and the day is not far distant when the Post Office Department of the government will prove a much greater blessing to the whole people than it is now. The suggestion of the Postmaster General for improvements in the department presided over by him are earnestly recommended to your special attention. Especially do I recommend favorable consideration of the plan for uniting the telegraph system of the United States with the postal system. It is believed that by such a course the cost of telegraphing could be much reduced and the service as well, if not better, rendered. It would secure the further advantage of extending the telegraph through portions of the country where private enterprise will not construct it. Commerce, trade, and above all, the efforts to bring a people widely separated into community of interest, are always benefited by a rapid intercommunication. Education, the groundwork of republican institutions, is encouraged by increasing the facilities to gather speedy news from all parts of the country. The desire to reap the benefit of such improvements will stimulate education. I refer you to the report of the Postmaster General for full details of the operations of last year, and for comparative statements of results with former years.

POSTMASTER GENERALS REPORT.

THE POSTAL TELEGRAPH

is by far the most important subject now inviting consideration in connection with the transmission and interchange of intelligence. The governments of the continental countries of Europe have, with few exceptions, claimed and exercised for years past the right of controlling and managing the electric telegraph, and in every instance with a degree of success commensurate with the care and attention bestowed upon their respective administrations. In Sweden, Norway, Russia, Bavaria, Italy, Turkey, Greece and Spain great advantages have been gained by making the telegraph a part of the public postal system; while in Switzerland, Belgium, the Netherlands, Prussia and France, where modern appliances and improvements have been more thoroughly utilized, the policy of governmental control has been fully vindicated. It remained for Great Britain to give a practical test of the public system as compared with the management of corporations and companies of private stockholders. After a protracted and most laborious investigation, Parliament passed, on 31st July, 1868, "An act to enable Her Majesty's Postmaster General to acquire, work and maintain electric telegraphs," which was followed on the 9th August, 1869, by an act providing money necessary to purchase the undertakings of the several telegraph companies in Great Britain and Ireland. On the 5th February, 1870, the transfers were effected, and the work of the postal telegraph began. At first serious difficulties were encountered by reason of the delay in passing the money bill and the inadequate preparations to accommodate the immense increase of business which immediately followed the large reduction of rates. These difficulties however, were soon overcome, and, thanks to the indefatigable and intelligent labors of Hon. Frank Ives Scudamore, second secretary, and his assistants, the advocates of the measure can already boast of its triumphant success. The charges established in the beginning were uniform throughout the United Kingdom, without regard to distance, and were fixed at the maximum permitted by law, that is to say, one shilling (twenty-four cents) for the first twenty words or part of twenty words, and three pence (six cents) for each additional five words or part of five words, exclusive of signature and address.

Some may hesitate to adopt this system in this country because of the great extent of our territory, the paucity of our population in certain large sections, and the great expense involved in extinguishing the rights of telegraph companies. The first two are the same objections that were urged for many years against all ameliorations of our postal service, nevertheless, postages have been cheapened and made uniform, and at the same time the postal system has been maintained and improved. Rightly viewed, the extent of the country is a strong argument in favor of a postal telegraph and the additional facilities and uniform rates it will afford. It is only in countries of large extent that the value of instantaneous, or nearly instantaneous communication can be appreciated. Who that desires to convey or acquire any information would hesitate beween sending a telegram from New York to California in seven minutes for twenty cents, and sending a letter in seven days for three cents?

It is true that a large sum of money will be required for the purchase of the present telegraph lines and their appurtenances. But if this be a difficulty delay only magnifies it; for, admitting that the government must at some time become the exclusive proprietor of the telegraphs, it is clear that every year will add to the amount of purchase money it will have to pay. The companies now in existence will extend their operations and new companies will be organized from time to time, all of whom would demand compensation for a surrender of their privileges and property. I therefore deprecate further delay as injurious to the public interests. The Post Office Department is now prepared to undertake the organization and management of the telegraph in connection with its other duties. Indeed, I believe that the department itself can aid materially in raising the the money needed for the purchase through Post Office savings banks if Congress will authorize their establishment. The security of the government being the best that could be obtained, many depositors would give it the preference over every other. By paying four per cent interest, at most, on deposits, a large fund could be readily accumulated and invested under the direction of the Treasury Department in the public securities. The proceeds of those investments could be used to reimburse the original purchase money and all other expenditures for construction and repairs.

To prove the feasibility of this plan, I recur to the history of the British office. Savings Banks in connection with post offices were established in Great Britain on the 16th of September, 1861, with a limitation in the law creating them, that they should not pay exceeding two and one-half per cent interest on deposits.

The total amount in hand after ten years' operation, and for which the British government pays only 2½ per cent interest, is £15,466,928, or $75,145,690—a much larger sum than will be required for the purchase and thorough repair of all the telegraph lines in the United States.

Convinced of the wisdom of establishing the postal telegraph and Post Office savings banks in the country, I earnestly recommend the passage by Congress of the laws necessary therefor. In my judgment those laws should provide as well for the absolute purchase of the lines and appurtenances of all telegraph companies in operation as for the exclusive right and authority of the government, after the several purchases shall be concluded, to conduct the business of transmitting telegraphic messages.

IN CONGRESS.

IN COMMITTEE OF THE WHOLE.

THE GOVERNMENT POSTAL TELEGRAPH PROJECT.

Mr. RANDALL, of Pa., called attention to that resolution which referred to a select committee all that portion of the President's Message, relative to the union of the telegraphic system with the postal service, and all other questions of subsidies to steamship lines. He did not see why that subject should not go to the Committee on Commerce or to the Post Office Committee. The owners of the telegraph lines of the country had estimated the cost of those lines to the government at $25,000,000. He had heretofore seen the evil effect of creating select committees to consider special subjects. He remembered that when the first Pacific Railroad committee was established, the Speaker of the House made it up in the interest of the railroads, and that that committee was prepared to give away all the land of the nation. He thought that this subject should take its natura course and go to the appropriate standing committee.

Mr. FARNSWORTH, Chairman of the Post Office Committee, moved that the subject be referred to the

Digitized by Google

Post Office Committee; not that he cared to have jurisdiction of the matter, but because it seemed to him that no other committee could have proper jurisdiction of it. He did not know what reason existed for the appointment of a select committee, although he was aware that a select committee on the same subject had been created during last Congress, and had arrived at no conclusion.

Mr. DAWES remarked that he had been on that select committee last Congress, and had joined in the minority report against the proposition. The experience which he then had had led him to believe that the subject was one of very great importance. It affected the treaty, the postal affairs and the foreign affairs of the country, so that no one committee could be said to have jurisdiction of the whole matter. It was a great subject, worthy of the consideration of the country, and which was being forced upon its consideration by the events and tendencies of the age. If anything required a special committee, which would have the time to consider it fully, it was this subject. If the gentleman from Pennsylvania (Mr. Randall) thought the Speaker had not the confidence of the House in the appointment of a select committee he might have a vote upon that question.

MR. RANDALL—I have nothing to say on that point further than I have said.

Mr. DAWES went on to say that he favored a select committee, not from any want of confidence in the Chairman of the Post Office Committee, or in the chairman of any other committee, or in any committee, but because he was convinced that the ramifications of the whole question were such that with no propriety could it be referred to any particular committee.

Mr. NIBLACK, of Ind., suggested that this project would entail immense patronage on the administration, which would have the appointment of at least 8,000 employes to take charge of the telegraphic business, which fact made the proposition an appalling one to him, and would control his vote against it.

Mr. DAWES admitted that there were undoubtedly difficulties in the way; but that fact rather rendered it more appropriate that the subject should be referred to a select committee.

Mr. NIBLACK conceded that there were many reasons why it should go to a select committee instead of a standing one, but he should be unwilling to trust any committee that was specially organized for the purpose. The temptation would be absolutely too great; the committee would have no other business to attend to, and would be the focus around which all influence would be brought to bear in favor of the scheme.

Mr. FARNSWORTH understood that it was proposed to incorporate with every Post office in the country that had a sufficient number of inhabitants, a telegraph office, and to make every Postmaster a telegraph operator, or else to appoint an expert to operate the telegraph. The government would thus have cognizance of all the private, confidential and financial business of the people. Every Member of Congress would be importuned by his constituents to make their Post Office a telegraph station. The Post Office Committee has been appointed without reference to this subject, and might, therefore, be presumed to be quite as fair as one that would be appointed specially. As a general rule, the best and fairest committees were the standing committees of the House. He was willing to admit that he had gone over the whole subject of postal telegraphs, and had for weeks and weeks listened to arguments for and against the proposition, and was against the whole scheme. The success of the system in Great Britain or any thickly settled old country, where no new post office had been established for fifty years, formed no criterion for this country and those institutions. The whole thing was monstrous in any way that it could be regarded.

Mr. BANKS, of Mass., remarked that the question of ocean cables was in the jurisdiction of the Committee on Foreign Affairs, and moved that that point be stricken off the pending resolution. (In this Mr. DAWES assented and the resolution was modified accordingly.) He did not think it absolutely necessary to have this subject referred to a select committee, although it involved questions of great importance. He thought it best for the interests of the country and for the business of the House, that select committees should be avoided whenever there was a permanent standing committee to which the subject could appropriately be referred.

Mr. BECK, of Ky., said he had been a member of the select committee which had had charge of the subject last Congress, and that the cost and effect of the project had been understated to-day. There were now some five thousand telegraph stations in the country, with seventy-seven thousand miles of line and seven thousand employes. Under the government plan there would be at least twenty thousand telegraph offices, one hundred and fifty thousand miles of line and twenty-five thousand employes. The gentleman from Pennsylvania (Mr. Randall), had understated the cost nearlyone-half.

Mr. RANDALL—I always like to be on the safe side.

Mr. BECK—And the gentleman from Indiana (Mr. Niblack) will find that instead of increasing the government officials by 8,000 they would be increased by 25,000. The minority of the committee had stated in its report last Congress the great objection to the project was that the government telegraph would be used for political purposes, through an array of officeholders. The facilities for thus using the wires would be a temptation so strong and would be so difficult to detect that it might well be doubted whether the administration would refrain from such use of them. I believe that the Committee on Appropriations is the proper committee to consider the subject, for that committee would be very careful in recommending anything that would take from the people not thirty-five millions but nearly seventy millions of dollars. He did not believe that the committee would ever sanction such a scheme or ever consider it for a moment.

Mr. RANDALL remarked that Mr. Dawes had, with his usual adroitness in debate, sought to place him in the position of finding fault with the Speaker. He would not take back anything he had said; but could reiterate the statement that the Pacific Railroad Committee had been composed originally, not by the present but by the then Speaker, of members avowedly in the interest of the railroad. It was customary when a select committee was to be appointed on any given subject, to choose a majority of those who were favorable to the proposition, and therefore he wished to stop this scheme of plunder right at the threshold. He was informed that originally the whole of the telegraph line had not cost more than two or three millions, and now the company had the effrontery to go to Congress and ask that its property be taken by the government at its present appreciated value. He would oppose the scheme, because if carried out, it would place the whole private and business transactions of the people under the scrutiny of government officials. The country had had enough experience of attempts of that kind, and he wished to have no further steps taken in that direction. He hoped that the House would squelch the thing at once. Here was a beautiful specimen of civil service reform, of which they had heard so much, increasing the employes of the government by 25,000 at one piece of legislation.

Mr. DAWES did not understand that there was any project recommended here. The statement by Mr. Randall, that the telegraph company asked Congress to purchase its property at an enormous rate, showed that that gentleman did not understand the relations of the matter any more than a baby. (Laughter.) The Western Union Telegraph Company was arraying itself with all it power and influence against any such proposition.

Mr. BECK remarked that while the Western Union Telegraph Company had opposed the project last Congress, he understood it to have changed its position, and to be now anxious for it.

Mr. DAWES said that that fact would not commend the matter to his approval, but this was not the time to enter into the merits of the whole subject. The only question was as to its reference.

THE SUBJECT REFERRED TO THE APPROPRIATION COMMITTEE.

After further discussion by Messrs. Palmer and Garfield, in favor of and by Messrs. Connor and King, in opposition to its reference to a special committee, the vote was taken and the subject was referred to the Committee on Appropriations. The vote was subsequently taken in the House, and the action confirmed—105 to 98.

IN THE HOUSE.

The committee of the whole having reported to the House, the matter was laid before it by a motion referring the matter of Postal Telegraphs to a special committee.

The ayes and noes were called for by Mr. Farnsworth. When taken, it was found the reference first called for was carried by ten majority, the vote being 105 for a special committee to 95 against it. This is considered a decisive victory by the administration men, because a majority of the committee will be favorable to the measure.

The fight was a spirited affair from first to last.

FROM THE NEW YORK TIMES.

Mr. Creswell's two great schemes of a postal telegraph system and Post-office savings banks will, if approved by Congress, depend greatly for their success upon the early introduction of a comprehensive scheme of civil service reform. We cannot, in such matters, calculate upon achieving equal success with other countries, unless we are prepared to adopt similar precautions for securing efficient service. The Post-office must be free from the control of the politicians if it is to prove capable of working out schemes truly national both in magnitude and importance. A splendid chance is presented by the proposed postal telegraph system for giving female labor a new field. In Great Britain lady operators are the rule; and, with the exception of a slight confusion at first, the plan has worked admirably.

FROM THE NEW YORK TRIBUNE.

We dissent most emphatically from most of the President's suggestions based on the Post-master-General's Report. We deny that the expectation that the Post-Office should sustain itself is unreasonable. On the contrary, we hold that the Government should pay its own pastage, just as others do, and that those who use the Post-Office should sustain it—by a fair and equal assessment of the expense on those who are benefitted by it. Let everything transmitted through the Mails be fairly assessed to meet

Digitized by Google

this expense; then, if three cents per letter does not pay, charge four or even five. But don't burden the Mails with thousands of tuns of free matter, and then make a parade of supporting the Department from the Federal Treasury. The system is every way vicious; and we are greived and amazed that the President still clings to it. Rip Van Winkle's twenty-years' sleep is a flea-bite to his.

Then as to "uniting the Telegraphic system of the United States with the Postal system," can the President be unaware that this means buying out the present stockholders in telegraphs at treble the cost of constructing the existing lines, and thus enriching a small number at the expense of the great body of their fellow-citizens? Thirty Millions are to be taken out of the Treasury by it to pay for property that never cost Ten Millions; and not one dollar of that Thirty Millions will ever come back again. Indeed, you tell us that the proposed system would "secure the further advantage of extending the Telegraph through portions of the country *where private enterprise will not construct it*" Not a doubt of it? Only throw the cost of extending and maintaining the Telegraph on those who don't use it, and we can have poles and wires, offices and batteries, superintendents and operators, where there is no business, and probably never will be. But, until the Post-Office is made to pay its own way, we insist that it shall let the telegraph alone. Nor will Congress vote otherwise, unless the members are plied with other than legitimate inducements to go wrong.

Of Mr. Creswell's scheme for placing the telegraphs under Government control we have spoken elsewhere. It is a mischievous plan, which we believe the good sense of the country will reject. Returns are cited of the great increase in the number of messages transmitted over British wires since they were united with the Post-Office Department; but the increase results from the reduction in tolls, and not from the change of management. Mr. Creswell could increase the consumption of bread if he would buy up all the bakeries and sell loaves at half price.

RAILROAD ITEMS.

From the Railway Gazette.

International of Texas.—The Houston *Times*, of the 16th ult., says that this road was then completed 46 miles east and four miles west of the point where it crosses the Houston & Texas Central, and is excellently constructed.

Fremont & Sandusky.—A Company with this name filed articles of incorporation with the Secretary of State of Ohio, November 16. It proposes to construct a railroad from Fremont, Ohio, through the counties of Sandusky and Erie to the city of Sandusky.

Southern Pacific.—This railroad, which now extends from Shreveport, La., westward through Marshall, Texas, 66 miles, is now the property of the Texas Pacific Company. The Shreveport *Gazette* says that it is now making a survey for a branch from Marshall, 42 miles west of Shreveport, nearly due north to Jefferson, Texas, about fifteen miles.

Burlington, Cedar Rapids & Minnesota.—This Company has commenced grading a branch line which will extend from Cedar Rapids nearly due north to West Union, Iowa, and thence northeast to a connection with Milwaukee & St. Paul at Postville.

St. Louis & Iron Mountain.—This Company's Arkansas Branch is now completed to Piedmont, 127 miles south of St. Louis and 50 miles north of the Arkansas border, and eighteen miles south of the recent terminus at Annapolis. Forty miles have been constructed this season (from Pilot Knob south), and most of the way through a difficult country.

The San Francisco *Chronicle*, of November 9, says: "The Central Pacific Railroad Company are now operating fourteen hundred miles of railroad, and are rapidly extending their lines in various directions. The San Joaquin Valley Branch, for which a subsidy was asked at the last session of the Legislature, is being extended southerly from Lathrop to Bear Creek, a point distant only 90 miles from Visalia, Tulare county."

Memphis & Little Rock.—The Pine Bluff (Ark.) *Republican* says that a contract has been executed in the sum of $2,000,000, providing for the immediate construction of the Pine Bluff Branch of the Memphis & Little Rock Railroad.

Montgomery & Eufaula.—This railroad is now completed from Montgomery, Ala., southeast to Eufaula, over the Chattahoochee River, a distance of eighty miles. Forty miles of it, from Union Springs to Eufaula, has been constructed this season. At Eufaula it connects with the Southwestern Railroad of Georgia, for Macon, Augusta, Savannah and the North, and where the western terminus of the Brunswick & Albany road will be.

Ulster & Ironton.—The Ironton (Mo.) *Enterprise* says: "We have a report that a thoroughly reliable company has been organized and the funds secured for building a railroad form Ironton to St. Mary's Landing on the Mississippi River, opposite Chester, Illinois. The length of road to that place would be about 45 miles, and would be the shortest which could be found to connect our mineral region with the coal fields of Illinois.

The *Courier* says: "The stock of this road has all been taken by English capitalists. The bankers in London will be Messrs. Blisschoffchein & Goldschmidt; Duncan & Sherman, of New York, will do the general banking business on this side of the water."

Erie & Genesee Valley.—This railroad is now completed from Mount Morris, in Livingston county, N. Y., southeast 24 miles to Dansville. The Erie Railway Company has leased it.

Pennsylvania Petroleum Railroad.—The Titusville *Courier* announces the letting of the contract for the construction of this railroad from Tidioute westward to Cambridge, Penn., about 40 miles, to Belden & Co., of Syracuse, N. Y. The route is from Tidioute, on the Oil Creek & Allegheny River Railroad, 38 miles northeast of Oil City a little south of west by way of Enterprise to Titusville, and thence northwest to Cambridge, which is a station on the Atlantic & Great Western road, 14 miles north of Meadville. A branch from Enterprise southward through Pleasantville and Shamburg to Pithole, 10 miles, is also let. It reports that an extension from Cambridge north to Erie, about 30 miles, will be let soon.

Marysville & Lexington.—This railroad is now in operation from Marysville, Ky., southwest to Carlisle, very soon will be completed to Millersburg, and in a very short time to Paris, Ky., thus opening a new route from the Ohio River to the famous blue grass region of Central Kentucky.

A survey is in progress for a railroad to commence at a point on the California Pacific, about ten miles north of Vallejo, thence crossing Napa Creek, near Green Island, skirting the salt marsh and crossing Petaluma Creek south of Donahue; thence *via* San Rafael to Saucelito.

TELEGRAPH LINES REPAIRED.

The telegraph line between Las Tunas and Santiago de Cuba, which for a long time has been interrupted by the Cuban insurgents, will be in working order again in a few days. The line between Las Tunas and Gibara, via Holguin, is already repaired and in working order. The line from Puerto Principe to Guayamara is nearly finished. The fact that these telegraph lines have remained undisturbed after being once placed in working order, is considered positive proof of the decline of the rebellion.

We are pleased to record the marriage of our good friend Robert Stewart, Telegraph Superintendent of the lines of the Camden and Amboy Railroad Co., to Mrs. Mary Cook, of Orange, N. J. The marriage ceremony was performed by Rev. N. Pettit, at Orange, Thursday, Dec. 7th, and we had the pleasure soon after of congratulating the happy couple at the Metropolitan Hotel, New York. We wish them abundant joy.

Springfield, Ill., Nov. 25, 1871.

To the Editor of the Journal of the Telegraph:

Dear Sir:—Your issue of Nov. 15 foreshadows a radical change in the tariff. A step that will eminently prove to be in the right direction, because *it tends to fix in the public mind, a definite idea of the cost of telegraphing.*

The masses of the people are but casual patrons of the telegraph. Under the present tariff system an individual telegraphs to-day, and may be again next week, or next month, by which time he will have forgotten the price he had previously paid. For these reasons the reductions of tariff made and making are not seen and are, therefore, not appreciated; except by those persons to whom the telegraph is a daily specific necesssity. This latter class is a small percentage of the aggregate community.

The number of messages transmitted yearly are several millions. It seems large, but on a little reflection it can be seen that it is comparatively insignificant. Assuming for instance that it is fifteen millions, and that the population of the country is forty millions: the average to each head will not reach three messages per annum.

Is there not room here for a vast enlargement of the business? Uniform, cheap rates will do it.

At present probably fully nine-tenths of the messages transmitted are *business* messages. The *social* element of the country has scarcely been touched. And here let me make a suggestion toward developing this social element, and I will have done with this communication:

Adopt a five-word base at half rates—messages over five and under ten words to remain as they are. Very little business, I opine, could be transacted within five words; and yet they would prove sufficient to express much pertaining to the weal or woe of a man's family. Yours, truly,

W. W. Kelchner.

Note.—We welcome all communications, especially those which come from experienced and intelligent managers. We cannot agree with our good friend Kelchner, respecting the use of a five-word rate. A large number of commercial messages are very brief, although the average of all messages is over thirteen words. To invite business by reducing the word standard seems in the inverse direction of true policy.

Paterson, N. J., Dec. 12, 1871.

To the Editor of the Journal of the Telegraph:

Will you please tell me, can a ground be tested on a circuit eight miles (or less) in length, and how?

Also please mention some good works on testing grounds, crosses, escapes, &c., and much oblige,

Yours respectfully, A Plug.

By "testing a ground," we suppose "locating" a ground is meant. This is becoming a familiar and easy process. "Pope's Manual" gives the usual modes of testing in such cases, and is sufficiently complete to answer all "A Plug" can desire.

Internal Resistance of Voltaic Batteries.—W. Betz, by the use of a compensating battery, has obtained and compared the resistances and electro-motive forces of various hydro-electric elements with great exactitude; and from those data has calculated the electro-motive force of various arrangements of voltaic batteries. Thus, taking a cell Daniell's battery as 1, the electro-motive force would be, according to his data:

1 Bunsen	= 1·799	Daniell
1 Grove	= 1·684	"
1 Stoehrer	= 1·272	"
1 Leclanche	= 1·167	"
1 Meidinger	= 0·849	"

—Poggendorff Annalen.

STAMP FRANKS.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
New York, November 17, 1871.

Executive Order, No. 133.

INSTRUCTIONS FOR THE USE OF STAMP FRANKS.

The conditions printed on the cover of each of these Franks are as follows:

CONDITIONS.

"This Frank is intended to cover only the personal and private messages of the holder and answers thereto. It is not designed for business or political communications.

"A stamp must be affixed to every message containing twenty words or less, not including address, date or signature, and an additional stamp for every additional twenty words or less.

"If the sender desires to have an answer returned free, he may Frank it by affixing to his message the stamps required under the above rule.

"The holder of this Frank, by accepting and using it, assumes all risks, and agrees that the Telegraph Company shall not be liable for damages, whether from negligence of Agents or from whatever cause arising."

INSTRUCTIONS TO MANAGERS.

The stamps are inclosed in covers, on which are inscribed the name of the person to whom the Frank is issued, and the territorial limits within which it should be used.

Each stamp bears the number of the book inclosing it, and all stamps issued to the same person during the year, will bear the same number.

Receiving Clerks should satisfy themselves, if possible, by inspection of the book, or otherwise, that stamped messages are signed by or addressed to the party to whom the Frank was issued. But they have no discretion to refuse a message when properly stamped, unless they have reason to believe that neither the address nor the signature is that of the Frankholder. A stamp is conclusive, unless there is evidence to the contrary.

It is proper, however, to call the attention of the customer to any violation of the conditions, in respect to territorial limits, or to the business character of the message offered. Gross abuses of privilege should be at once reported to the Superintendent.

Anything in Executive Order, No. 119, conflicting with the above, is hereby revoked.

WILLIAM ORTON, President.

After quoting Mr. Orton's letter, the *Evening Mail* remarks: "We always thought that the Western Union was managed with as much shrewdness and practical wisdom as any other company in the country. We are confirmed in our opinion."

THE plan of the Titusville *Herald* to find oil fields won't do. The earth is a great conductor, and the intervention of a petroleum lake between two points would make no obstruction, so long as there remained masses of moist earth round them. The conductor being infinitely large, the minor obstruction could not be perceived. Were both the terminal plates by some lucky chance immersed in the same oil pool, if petroleum be proven to be a non-conductor, the result might be apparent. Petroleum is a good conductor.

THE POSTAL TELEGRAPH SCHEME.

The President's recommendation to add the telegraph service to the functions of the national government has surprised the country. Public opinion condemns the project without hesitation and with remarkable unanimity. We have yet to hear any important expression in its favor.

It is evident that President Grant regards the condition of the national civil service with a complacency not shared by other citizens of the country, if he can conscientiously recommend so important an extension of its functions. For a long time the people have been demanding reforms in this department of the government. The people might very fairly respond to the recommendation of their chief magistrate in these words: "When, by a proper use of your ample powers, you have rendered the civil service something better than an instrument of political influence, it will be time enough to urge this vast extension of its powers."

But even if our civil service were in a condition less deplorable than it is, there would be strong objections to an assumption by the government of the telegraphic business of the country. It has become a principle of political science, deduced by costly experience, that governments, lacking the spur of private interests, are wasteful and inefficient agents in conducting business. Therefore they should be strictly limited to functions which private enterprise cannot perform, or which, for political reasons, should not be entrusted to individuals. The necessity of this rule is less when a well-organized civil service exists; but with that department of our government in its present condition, or in any condition it is likely to reach for a number of years, the strict limitation of the duties of government should be insisted upon.

The power of controlling and directing public opinion and action in any important crisis, which an exclusive possession of telegraphic communications would afford, would strongly tempt public officers (already too willing to adopt doubtful methods in politics) to suppress intelligence or even temporarily to deceive the people for partisan purposes. Until the American standard of official integrity and self-respect be greatly elevated; until sharp practices are less frequent in our politics, the people cannot safely make the government the purveyor of their information.

Nor is there any reason to increase the occupations and responsibilities of our government by the proposed measure, unless it appears that the private organizations now owning and managing the telegraph lines are incompetent or untrustworthy. This is not alleged by the advocates of the scheme. It is not for the remedy of existing evils, but in the hope of securing certain additional advantages, that the project is urged. Among these, at once the most desirable and the most doubtful, is greater cheapness in the transmission of messages. The government would undoubtedly reduce the rates. But such a reduction would not necessarily lessen the cost of the telegraph system to the people. The funds necessary to maintain the telegraph lines, if not raised from tolls, must be realized by taxation, as in the case of the Post Office Department.—*N. Y. Evg. Post.*

OFFICERS.—A meeting of the Telegraph Snow Shoe Club was held the other night for the purpose of electing officers for the ensuing season. The following gentlemen were elected officers:—Mr. J. Dakers, Hon. President; Mr. Angus Grant, President; Mr. W. Bowman, Vice-President; Mr. W. Mathews, Secretary and Treasurer; Messrs. McIntyre, J. Cochrane and W. Wilson, Committee. The Club commenced its weekly tramps on Friday night, December 1.—*Montreal paper.*

LELAND'S GALVANIC BATTERY.

This invention has for its object to produce an electric battery which will operate continuously without requiring attention, as long as it remains provided with the requisite exciting substances. The invention consists in placing within the porous cup, containing the platinum element, sulphate of mercury alone or mixed with black oxide of manganese, and in surrounding the cup with water, which is in contact with the zinc, This combination, it is claimed, produces reliable action, and is very economical, as the spent sulphate of mercury falls to the bottom of the cup in a shape to be readily reconverted.

The inventor states that, by connecting the poles of the platinum and zinc plates, a steady action is maintained until the sulphate of mercury is entirely decomposed and falls to the bottom of the cup as metallic mercury, ready to be reconverted into sulphate of mercury. This insures great economy.

This battery will, it is claimed, work weeks or months without attention, except perhaps the filling up of evaporated water, and the supply of sulphate of mercury. No acid being required, offensive fumes are avoided, and much steadier action is insured.

The improvement is the invention of Mr. Edwin J. Leland, of Worcester, Mass.

THE correlation of vital and physical forces continues to be a subject for phylosophical research; and among points of interest, there is none more interesting than that which relates to thought and its manifestations. It is evident, say the investigators, that the mechanism for the production of deep thought, effects the conversion of energy far more perfectly than that which produces simply emotion, When a thought is expressed by some outward action, there is a less development of heat than in contrary cases—that is, when no muscular movement takes place. Experiment has shewn that the amount of heat developed by the recitation to one's self of emotional poetry, is in every case less when the recitation is oral—that is, muscular expression. This accords with the well-known fact, that emotion often finds relief in physical demonstrations, which diminish the emotional energy by converting it into muscular.

On this question, Professor Barker, of Yale College, remarks: 'Chemistry teaches us that thought-force, like muscle-force, comes from the food; and demonstrates that the force evolved by the brain, like that produced by the muscle, comes not from the disintegration of its own tissue, but is the converted energy of burning carbon. Can we longer doubt,' he adds, 'that the brain is a machine for the conversion of energy? Can we refuse to believe that even thought is, in some mysterious way, correlated to the other natural forces, notwithstanding that it has never yet been measured.'

IN brief dispatches intimations of a strike among the telegraph operators of Great Britain are given. The cause, so far, is not named, but the strike is a failure.

A CARD.

I take this method to express my most grateful and heartfelt acknowledgements to the many friends who so signally manifested their kindness and regard for me, in the presentation of a generous purse, containing upwards of two hundred dollars, contributed by operators of Boston office, operators, officers and employes of Providence and Worcester road, and citizens of Uxbridge. I would also return thanks for the many favors administered by the hand of friendship, which did so much to alleviate the suffering and dispel the gloom of the sick room.

LUCELLA W. STONE, Telegraph Operator.
Uxbridge, Nov. 28, 1871.

FAMILIAR TELEGRAPH TALKS.

HEALTH OF OPERATORS.

This subject is scarcely in the order we designed it to occupy. Yet, because of others, we now give it. It may seem out of due range. We would however, be remiss to what we conceive to be a duty, did we omit to convey intelligence respecting anything which can, in the least degree, confer substantial benefit or pleasure upon any of our readers. We conceive it the duty, and ought to be the instinctive pleasure of every one, to use the experiences of his life which have been to him fruitful of health to brain or body, so that his fellows can share their benefits.

An article we wrote several weeks ago respecting the lift cure, has brought to us considerable correspondence and inquiry. To most of these we are unable to reply by letter, and we, therefore, prepose to do so by giving all the information within our power so that all can have it. We shall also give the story of our own experience with this caution. We were probably in the physical condition which made this process the very thing adapted to us. Let nobody think that lifting is going to give him immortal youth, or will atone for neglect of the body in food, clothing and rest. However here is our story :

Towards the middle of September we found ourself in a state of health which could not be called sickness, in which food was acceptable though not greatly desired, the power to sleep moderate, yet the action of the body irregular, and its vitality low. The feeling of power was absent. There was no resistance, no flash, no force, no vim. The hot Scotch blood had lost its fire. We were discouraged, weak, broken. Nothing seemed before us but retirement from our duties and an effort to regain lost power by dropping every care and forsaking all toil. Nay, it sometimes flashed across us that life's rubicon had been passed, and that in a series of gradual settings we would soon reach the rest for the weary, and, beneath the daisies, sleep. Even that had its lustre, and worse things happen to men than to have the green earth blossoming above them. Yet we had a dislike to leave, and thought that, little as we might be thought of or needed, we would like to stay a little longer.

One evening, having left the office, the sense of weariness was painfully present. The distance to our home seemed vast and far. There came, we confess it, a tear upon our cheek, a token of utter exhaustion, and we stood for a few moments on the sidewalk a prey to its power.

In the block below us, there is what is called the "Butler Lift Cure" of which we had heard, but which we had regarded as some long haired man's notion, and to which we gave no concern. Impelled now, however, by our condition, we ascended to the room, and entered into conversation with the principal respecting the process. On his recomendation we ascended the platform and lifted consecutively 120, 130, 140 and 150 lbs., by an arrangement which the cut given will convey a correct idea. In no other attitude could we possibly have lifted so much. It was the very extent of our capacity. After reclining on a lounge a few minutes we started for home. It is no exaggeration to say that on regaining the street our sense of exhaustion had entirely left us, not the slightest sense of fatigue accompanying us on our way home. Here seemed something wonderful. It was noticed the instant we met our household. Brightness had come to the eye, and elasticity to the step. We found too that we could laugh, and supper tasted like a beatitude. We are not romancing a particle.

Since then we have spent a half hour each day in this way greatly to our benefit. It has brought into exercise the entire body. Headache, pains in the eyes, weariness in the breast, torpidity of liver, irregular action of the bowels have one by one disappeared. We have just returned from lifting 350 lbs., and feel as if we had just arisen from refreshing sleep. All this to us is simply wonderful. The deep lines in our face have disappeared. Our friends recognize the change, and the members of the Telegraphers Mutual Life Insurance Association are relieved from the near propect of an assessment for the benefit of our heirs.

It is asked how we proceed. We will tell you :

1. Two lifts at short intervals of a comparatively light weight, say 120 lbs., the body while lifting being preserved strictly straight, the breast well out. It is an ease in lifting to first inhale a full breath, and, for a time, retain it. For heavier lifts this is essential, and much aids the invigoration of the body, expanding the lungs, and bringing all parts of the body into exercise in the act of lifting.

2. After a short rest, two lifts of say 140 lbs. each. Succeeding these, complete rest upon a lounge, with head low, for about five minutes, is practiced to allow reaction, and the quieting of the body.

3. Two lifts follow, of say 160 lbs. each, followed by maximum lifts of say 175 lbs., and succeeded by a rest of the extended body on a lounge for about 10 minutes. These weights to be gradually increased, say five pounds daily, so long as they can be lifted without oppression.

So far as we can discover, the exercise of the body in these lifts is complete and uniform. Gentlemen far advanced in years we find each day enjoying its invigorating effects, and many young men also practice it, who credit it with restored health and prolonged life.

The cost of a complete "Butler Lift Cure" apparatus and weights is $200, and can be had in a modified form as low as $50. Of these modified forms we have no knowledge.

There is another method of lift which we think better adapted to the use of offices than the one described, only, however, because of its being without weights, easy of change from one power to another, and of a price which, in the case of large offices, is quite within the means of those connected therewith. It is supplied with two handles, to be lifted as one would lift a wheelbarrow. This renders it suitable for ladies. By standing on a small platform and lifting at the handles, one raises his own body, and the amount of lift is arranged by an adjusting yoke, easily changed. Price $80.

In this exercise there is complete action given, in a quiet and careful manner, to the whole body. It requires only a few minutes daily, and, we believe, largely conserves health.

RAILROAD WIRES.

THEIR USES AND THEIR ABUSES.

Every road now has its train dispatcher, and where there are two or more wires, one of them is especially devoted to train work. Some of our roads, however, have but a single wire, and over this wire must pass the telegraph company's business, as well as that of the road. Others again have two, three, and four wires, following the track, while, perhaps, more than half the officers on the line have only one instrument, and this instrument is of necessity kept on the train wire. So, in either case, the railroad wire is demanded more or less for the transmission of paid business; and if a proper economy in its use be exercised by the train dispatcher—who usually has charge of the circuit—the business of neither corporation need suffer any serious delays. It is right here that we wish to point out one of the abuses of railroad wires—a very common abuse, though one not wholly unexceptive. We refer to the manner of sending train orders as it is generally done. A telegraph order giving a certain train the right to the road ahead of, or against another train, must of course be sent to the conductors of both the interested trains. But instead of making one order answer for the two trains, and calling up both officers and having them copy at the same time, it is customary first to send an order to the train against which the time is given, and then to send another order to the train in whose favor the special arrangement is made, thus occupying the wire just doubly as long as there is any necessity for. A great many of our railroad operators are also station agents, or have other duties to perform, and as a class they are not skillful in the Morse profession, hence, working with them is often slow and tedious, and on roads where from twenty to fifty train orders are issued daily, the time consumed by such useless repetitions ought to be saved in the interest of other business. We say this abuse is not wholly unexceptive. We can point to roads that have long since abandoned, if indeed they ever adopted, this primitive usage, and one such road, at least, is running at the present time not less than one hundred trains daily, most of them over a single track. They find one wire more than sufficient for train work. This would not be possible did they transmit every order twice.

Executive Rooms, Western Union Tel. Co.,
145 Broadway, New York.

NEW YORK, DECEMBER 15, 1871.

THE POSTAL TELEGRAPH.

One of the most prominent of the measures of the administration recommended to Congress, both by the President and the Postmaster General, as will be seen by our published congressional proceedings, is the establishment of the European system of Postal Telegraphs, as a part of our governmental system. It will be urged and opposed with equal vehemence. Its discussion has already given a chance to vent as much mis-statement of fact and false assumption as have heretofore attended it. To one of these we find the following official denial:

"NEW YORK, Dec. 6, 1871

"Hon. JAMES B. BECK, M. C., Washington:

"You are reported in the morning papers as having stated in the House yesterday that, whereas the Western Union Company had opposed the assumption of the telegraph by the government before the last Congress, you understood it to have changed its position and to be now anxious for it. Permit me to assure you that you have been misinformed. The Western Union Company is inflexibly opposed to any interference of the government with their business. A meeting of the Board of Directors was held this morning, which was largely attended, and a resolution was unanimously passed protesting against the right and the policy of any acquisition of their property and rights by the government. A committee, consisting of Mr. Horace F. Clark, Mr. A. B. Cornell, Mr. Edwin D. Morgan, Mr. Moses Taylor and myself, were appointed to prepare and send to Washington a protest against the suggested action of the government, and to claim its protection against interference and against the policy of the establishment of competitive enterprises."

WILLIAM ORTON, President.

To misrepresentations respecting the value of the lines and the schemes of their owners, it would be waste of time and space to allude. We reprint an extract from Herbert Spencer, which we regard as the vital argument in the whole case.

Herbert Spencer says: "While representative government is, by its intrinsic nature, better than any other for administering justice or insuring equitable relations of citizens to each other, *it is, by its intrinsic nature, worse than any other for all the various additional functions which governments commonly undertake.* To the question, 'What is representative government good for?' our reply was, 'It is good, especially good, good above all others, for doing the thing which a government *should* do. It is bad, especially bad, bad above all others, for doing the things which a government should *not* do.'

"To this truth we may add a correlative one. As fast as a government, by becoming representative, grows better fitted for maintaining the rights of citizens, it grows not only unfitted for other purposes, but dangerous for other purposes. In gaining adaption for the essential functions of a government, it loses such adaption as it had for other functions, not only because its complexity is a hindrance to administrative action, but also because, in discharging other functions, it must be mischievously influenced by class bias. So long as it is confined to the duty of preventing the aggressions of individuals on each other, and protecting the nation at large against external enemies, the wider its basis the better; for all men are similarly interested in the security of life, property, and freedom to exercise the faculties. But let it undertake to bring home positive benefits to citizens, or to interfere with any of the special relations between class and class, and there necessarily enters an incentive to injustice. Therefore do we say that *as fast as representation is extended, the sphere of government must be contracted.*"

These sentiments are our own. We believe in the old democratic motto, "That government is best which governs least." We protest against an interference with popular enterprise which must, in the nature of things, injure both government and people. Especially do we resist that which, if assented to, would be an admission that the purity of representative government is less dear to us than the mere cheapening of a commodity which, by the pressure of public opinion, the general relation of other values, and an intelligent management, sooner or later finds its true status and limitation.

AT the regular semi-annual meeting of the Board of the Western Union Telegraph Co., held December 6th, Geo. H. Mumford, Esq., Secretary, was unanimously elected Vice-President. It is a post requiring much tact, and of great labor, to which Mr. Mumford brings a sound constitution and ample ability.

In a meagre and unsatisfactory message, via Jamaica, the restoration of the lost or broken cable between Jamaica and Porto Rico is reported to have been effected, although telegraphic communication thereby "cannot be opened until the arrival of the cable steamer International from London," supposably from the necessity of material or additional cable to make the connection complete, or to repair a new break which is reported 28 miles from Porto Rico.

With the knowledge that an unsuccessful attempt had been made to connect the Porto Rico cable with St. Domingo, in which the main cable was broken, we are led to regard the dispatch from Jamaica as referring to this break and not to one near Porto Rico. Shore cable is needed to make the contemplated loop with St. Domingo, which the International probably bears.

There now seems some promise of an early telegraphic communication with South America, and with the large family of islands which form the curiously arranged stepping-stones of the Indian Ocean between Cuba and Venezuela, unless new misfortunes attend this unfortunate enterprise. Connection with the telegraph systems of South America will, of course, soon follow the successful connection with Porto Rico.

We have before us the report of the West India and Panama Cable Co., for the the year ending, September 30, 1871. Of the capital of £650,000, there has been issued:

	£	s.	d.
Sales of Stock	571,910	0	0
Debenture Bonds issued	27,000	0	0
Paid up Shares held against contractors	78,090	0	0

The expenditures of all kinds up to the date of the report, including £37,874, the cost of the unfortunate steamer Suffolk amounts to £609,650 14s. 2d.

The operation of the cables successfully laid had, so far, left a deficit of £983 6s. 3d., which, with the limited range of communication, and a high tariff, bitterly complained of by the population, is not to be wondered at.

The cables which have been successfully laid connect Porto Rico, St. Thomas, St. Kitts, Antigua Guadeloupe, Dominica, Martinique, St. Lucia, St. Vincent, Barbadoes, Grenada, Trinidad and thence to Georgetown, Demerara, whence the land line is completed to Berbice. The land lines in Trinidad are in working order and those in Guadeloupe are reported as almost complete.

The cable between Jamaica and Panama remains broken in Latitude 14, 12 N, Longitude 77, 45 W; over 300 miles additional cable is required to complete this connection with Jamaica, provided the cable already down is recovered.

The Directors make the following statement to the shareholders:

"The Directors cannot help expressing the very great regret they feel that the Contractors have so long failed to complete their contract. The difficulty in which the Directors are placed, owing to the present incomplete state of the Company's Submarine Telegraph system, is enhanced by the fact that it accidentally came to their knowledge in April last, that Sir Charles Bright, whose services as Engineer of the Company they had thought themselves fortunate in securing, *had accepted the position of sub-contractor for laying the cable.* As soon as this came to the knowledge of the Directors, they acquainted Sir Charles Bright of their having been advised that his office as Engineer *became vacant from the date of the sub-contract.*" They add:

"It is at present injudicious to point out the course which your Directors will have to pursue to protect your interests. They trust the Contractors will soon fulfil their contract, and that no difficulty will be made by them in making due reparation for the losses this Company has sustained."

It thus appears that although the contract was originally made with the India Rubber Telegraph Works Company, it practically fell into the hands of private parties, to which we formerly alluded, or, what is more strictly correct, perhaps became partners in the undertaking. This is confirmed by the fact that Sir Charles Bright, at the meeting of shareholders, held in London, Nov. 22, denies that he acted with the contractors without the knowledge of the Directory. Whoever the sub-contractors are, it seems impossible but that large loss must have attended the undertaking. The cost of steamers waiting, with banked fires, week after week, and month after month, for lulls of weather to attempt the restoration of cables, inadequate vessels, one of which, the "Suffolk," was an old blockade runner, bought cheap and fitted for cable service, all intimate a heavy damage to the contracting parties. The "Suffolk" which was leased to Sir Charles Bright, for £3,000, for an unlimited time, is now on her way to Key West to recommence her work.

We yet hope for ultimate success. The cable-makers, we are told, have a majority of the stock.

Rear Admiral Hugh Dunlop, C. B., has been appointed commissioner to investigate the causes of delay in laying the cables.

The *Standard*, London, Nov. 24, 1871.—It is understood that the recent advance in the shares of the TELEGRAPH CONSTRUCTION COMPANY has been occasioned by the arrangements in progress for securing the contract of the new Brazilian cable direct from the government. In addition, it is known that projects are in contemplation for further Atlantic cables, so that the service may always be kept up without the slightest interruption.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
New York, December 6, 1871.

CIRCULAR TO TRANSFER AGENTS.

On the 31st December inst., at the close of business, all Cipher B books and sheets now in use by Transfer Agents and Offices, will be cancelled and annulled and a new set of books and sheets substituted in lieu thereof.

You will receive, herewith, a new book for your use on and after the 1st January, 1872, containing your Cipher B sheets, with all other Transfer Agents, and with all Transfer Offices in your District. You will also receive loose sheets, intended for the new Cipher B sheets of the Transfer Offices in your District, and to be forwarded to the Managers of such Offices as hereafter directed.

These sheets are all numbered and are duplicates of the pages referred to in the index of your book opposite the names of the offices—For example: Opposite the name Ashland is set the figures 51, which indicates that page 51 represents the Cipher B sheet of the Ashland office; you will therefore forward *the loose sheet numbered* 51 to the Ashland manager, with directions to use the same as his Cipher B sheet, from and after the 1st January, 1872, and to return his old Cipher B sheet to you at the close of business on December 31st; so with all other Transfer Offices in your District. You will observe from the index of your Cipher Book, that two pages instead of one, have been assigned to each Transfer Agent for his Cipher B sheets with all other Transfer Agents—one page to be used in *sending* and the other in *receiving* transfer messages.

For example: In sending a transfer message to another Agent, you ascertain the proper Cipher B word to be used therein, by reference to the page specified in the "*send*" column of the index opposite the Agent's name—and in receiving a transfer message from another Agent, you verify the Cipher B word used therein, by reference to the page in the "*receive*" column of the index, opposite the Agent's name.

In the old cipher books only the first thirty pages correspond in all books, but in the new cipher books *all* the pages correspond in all books, so that whenever the cipher words, either on a "*sending*" or a "*receiving*" Cipher B sheet, between two Transfer Agents, have been nearly all exhausted, the two Transfer Agents interested can agree upon and substitute any other unappropriated page in the book to be used in place of the old one, for sending or receiving, as the case may be.

If any Transfer Agent should deem it desirable, he may appropriate two pages—one for sending and one for receiving—for use between himself and any office in his district doing a large amount of business; but as a general rule, one sheet will be found enough between Transfer Agents and their Offices for both sending and receiving transfer messages.

Whenever all the pages in a cipher book have been appropriated, the Transfer Agent will make application for another book, which will be furnished him from this office.

No change whatever, is contemplated in the general or special cipher instructions now in force.

Transfer Agents will acknowledge, by telegraph, the receipt of new cipher books and sheets, and will return their old cipher books and sheets to this office as soon as practicable, after the new ones have gone into operation.

GEO. H. MUMFORD, Vice President.

From the recent official reports to the Mexican Congress, the following statistics of the railroads and telegraphs of that country are taken:

RAILROADS.	Length. Kilometers.	Meters.
From Mexico to Puebla	186	278
Vera Cruz to Paso del Mosho	75	...
Vera Cruz to Loma Alta	35	...
Vera Cruz to Medillin	12	...
Mexico to Tacubaya	8	...
Mexico to Tlalpan	24	250
Mexico to Guadaloupe	6	700
	347	228

Or 216 miles.

LINES OF TELEGRAPH.	Length. Kilometers.	Meters.
From Mexico to Cuervanaca	83	800
Mexico to Toluco	67	40
San Luis to Zacatecas	184	360
Zacatecas to Durango	54	470
Tehuacan to Oaxaca	272	350
Vera Cruz to Tampico	288	500
Mexico to Vera Cruz, Tehuacan, Tlavcula and Tulancingo	1,047	500
Leon to Guadalajara and Manzanillo	646	260
	2,643	280

Or 1,642 miles.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
December 15, 1871.

Notice to Special Transfer Offices.

Amounts received at special transfer offices, for transfers of sums exceeding one hundred dollars, will hereafter be remitted direct to the Treasurer, in New York, in the same manner as they have been sent heretofore to the Transfer Agent at that office.

On and after 1st January, 1872, Mr. I. C. Hendrickson, of the New York office, will take charge of the Transfer Districts previously assigned to Mr. Horner and Mr. Holmes, and all transfers for offices in those districts and for special transfer offices will be addressed to him.

The following changes will be made in the list of transfer offices on same date.

NEW TRANSFER OFFICES OPENED.

ADDITION TO LIST OF SPECIAL TRANSFER OFFICES.

Washington, D. C.	I. C. Hendrickson

Transfer Agents of Districts in which the new offices are located, will forward to the managers of such offices, complete sets of the forms required for the service, which forms will be furnished them from this office on the usual requisition.

These forms should be forwarded, at least a week in advance of the first of January.

Managers of offices dropped from the list, should be required to return the money order forms in their possession, to their Transfer Agents, at the end of the year.

Each transfer office will be furnished with a printed and framed list of the money order offices of this Company, to be hung up in a conspicuous place in the office.

All requisitions for transfer blanks or books (ciphers excepted) will be made hereafter on the Supply Dept. at New York.

GEO. H. MUMFORD, Vice President.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
December 15, 1871.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since Dec. 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

OFFICES HAVING "SPECIAL SHEET A,"

Will hereafter check Brunswick, Ga., 25 cents more than "Special rate" to Savannah, Ga., and to Macon, Ga., same as "Special rate" to Savannah, Ga.

ATLANTIC CABLE BUSINESS.

Notice is given that the Shanghai and Nagasaki Cable is repaired, but the section from Hong Kong to Shanghai is now broken.

Messages for Shanghai, via Falmouth, must be addressed, "*Post Hong Kong.*" Rate as before to Hong Kong, $35, adding 38 cents for postage.

Messages for Nagasaki, via Falmouth, addressed, "*Post Hong Kong, telegraph forward,*" which words must be charged for, will be sent by cable from Shanghai. Rate is $40 for 20 words, and half rate for extra ten, or fraction of ten, with 38 cents added for postage from Hong Kong to Shanghai.

The communication with Nagasaki by Great Northern and Siberian lines is still open for messages specially addressed "*via Russia.*"

Telegraphic communication is now open with the following stations in the Shetland Islands:

Moss Bank in Mainland,
Culla Voe in Yell,
Uga Sound in Unst,
Balta Sound in Unst.

Rate from London:

50 cents for 20 words or less,
25 cents for each 10 or fraction of 10 words over 20.

The 10 word Continental rate to India, Aden and Persia, is abolished. The minimum charge is now for 20 words, for which the rate remains unchanged—viz:

From London—	*For 20 words or less:*
To Aden	$15 00
To India	22 50
To Farther India and Ceylon	23 50
To Persia, including Bashire	6 12

Half rates for each 10 words or fraction thereof over 20.

The words "via Teheran" will not henceforth be charged for beyond London.

WILLIAM ORTON, President.

CORRECTION.

Supt. W. A. L'Hommedieu's headquarters are at Monroe, La., instead of at Shreveport, La.

A number of items designed for this number are unavoidably omitted.

A cotemporary says the new word "cablegram" "knocks on the cover of the dictionary for admission."

THE price of the Morse Testimonial Monographs, packed on rollers and post-paid, is $1.25. The engrossers design leaving copies in our hands ready for mailing when orders are sent us, and to which we will gladly attend.

DEATH OF C. F. V. RANDALL.

The St. Albans (Vt.) *Messenger* referring to the recent death of Mr. Randall, says:

"After acquiring such an education as the public schools of Northfield afforded, Mr. Randall learned the art of telegraphy and was employed at Northfield, White River Junction and Rouses Point, prior to his coming to St. Albans some seven or eight years since. In every place he made many friends and no enemies, and being expert and faithful in his business, won the position of chief operator at this most important station. He was offered by Gen. Butler, when in command at New Orleans, the best place and highest pay in his department, but was persuaded by Gov. Smith to remain here. Last year, on the promotion of Geo. L. Stone to be one of the division superintendents of the Vt. Central, Mr. Randall was made the master train dispatcher of the entire line—a position which he filled in the most masterly manner."

The *Free Press* adds:

"'Death loves a shining mark,' and in this instance the point is made complete. His loss, which must be almost irreparable to the railroad managers, is severe among his many acquaintances also. He was one of the best boys we ever knew, of honest and correct habits, from one of the best Vermont families. Modest and retiring, he was capable and true, and a gentleman in the best sense of the term. He was highly respected by his associates and by newspaper men especially, who ever remember his courtesies and genial good qualities."

Mr. Randall was not a member of the Association.

IT seems that the pleasant story respecting Miss Josie Mitchell, of St. Charles, Mo., is a hoax, for which some imprudent operator ought to be made to *Swett.*

OUR friend Purnell, of Opelika, Ala., has left his express duties, and now devotes himself loyaliy and exclusively to the telegraph service.

TO REVIVE THE COLOR OF BLACK CLOTH.—Take of blue galls, bruised, four ounces; logwood, copperas, iron filings, free from grease, and sumach leaves, each one ounce. Put all but the iron filings and copperas into one quart of good vinegar, and set the vessel containing them in a warm water bath for twenty-four hours, then add the iron filings and copperas and shake occasionally for a week. It should be kept in a well-corked bottle. It may be applied to faded spots with a soft sponge. It is good also to restore the black color of leather when it turns red, the leather being previously well cleaned with soap and water.

THE ANNUAL REUNION OF THE TELEGRAPHERS OF CENTRAL AND SOUTHERN NEW YORK.

The place designated for the meeting this year being at Elmira, a party of nine telegraphers from Syracuse, Rochester and Auburn, left here on the afternoon of the 29th, reaching Owego on time. They were met and escorted to the Central Hotel, where, after friendly greetings were exchanged, the party partook of a bountiful supper. Leaving Owego Thanksgiving morning at 7:20, they were joined on the train by brother operators from Binghamton, Susquehanna, New York, and other points east.

On arrival at Elmira, our party were met by Messrs. Berry and Lewis, of the Erie R. R. Telegraph; Palmer, Garnsay and Putnam, of the W. U. Telegraph, and Easterbrook, of the Northern Central R. R. Co., all of Elmira.

After warming up, the party returned to the depot to meet Western telegraphers, who arrived at 12:03; then back to the Rathbun House, more telegraphers joined the party, making the number between thirty and forty. At one the party repaired to the spacious dining-rooms, where a huge repast was served. After dinner the party went below to the W. U. telegraph office where greetings were sent to L. Tillottson, of New York, formerly Superintendent of the Erie Telegraph lines, and to the present Superintendents of the 7th and 9th divisions, after which the party were invited to a drive. At 4:30 they proceeded to the depot, where a comfortable room was tendered for their use by Supt. Gardiner, to which the party adjourned.

Mr. Graham being called on, responded by thanking the Erie boys for their hospitality, and proposed that these meetings should be made an "annual institution" hereafter, to be held on the line of the N. Y. Central and Erie, and he proposed that the next meeting should be held at either Syracuse or Rochester, Thanksgiving, 1872.

Mr. Angell, of New York, extended an invitation to hold the meeting at New York.

Mr. Berry, of Elmira, took the floor, stating that he took great pride in these reunions, and hoped they would be imitated throughout the country by the telegraphers, and thought that by becoming personally acquainted, there would be a better spirit and feeling over the wires, and everything in our business would be more harmonious.

While accepting the invitation to visit Syracuse, he would remind the boys of their last two meetings in cold weather, and suggest that the day should be changed to July 4th, which, being a holiday, will give us as good a chance to be present as on this day, and as every city or place was in its full beauty at that season of the year, it would be more enjoyable.

Motion to change the day being seconded, it was carried unanimously.

BORN.

To Chas. M. Kinnaman, manager W. U. Tel. office, Tiffin, Ohio Dec. 2d, a son.

MARRIED.

EDSON—HAZELTON.—At Johnsontown, N. Y., Nov. 15, by Rev. C H. Baldwin, Hubert S. Edson, manager W. U. and Erie Railway Telegraph, Corning, and Miss Delia Hazelton, both of Corning, N. Y.

VENABLE—FORREST.—At Towanda, on Dec. 6th, at the parsonage, by the Rev. S. J. Lusk, E. A. Venable, of Oxford, N. J., now operaror Dispatcher's office Pa. and N. Y. R. R., Towanda, to Miss Nellie Forrest, of the latter place.

DIED.

BUTLER.—In Plymouth, Dec. 5, of consumption, Thomas D. Butler, aged 20 years and 4 months.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 3. NEW YORK, JANUARY 1, 1872. WHOLE NO. 100.

TELEGRAPHIC COMMUNICATION WITH CHINA AND JAPAN.

THE rival advantages of submarine and over-line telegraphs between England and the Far East are about to be put to a very practical test—that of competition. The China Submarine Cable is really submarine for the whole distance from Falmouth to Hong-Kong. The new line—the Great Northern—which is now brought into operation, is carried through Russia, Siberia, the Amoor, and so on to Wladiwostok, on the Pacific, a distance of some 6,000 miles by land. The advantages of a submarine cable over a land line are too apparent to need a lengthy notice. There is not the same liability to mistakes in transmitting messages from intermediate stations, nor the delay required for such subsidiary messages, and not the same liability to interruption by winds or floods. In order to counteract the effect of this inequality, we understand that the Great Northern Company intend to convey messages at £4 6s. instead of £7, the present rate by the Submarine. This tariff will probably turn out to be a pretty fair estimate of the comparative value of the two lines. The Submarine has for weeks past brought daily messages from Hong-Kong in from five to seven hours, which, allowing the difference of time between London and Hong-Kong, practically amounts to a gain of time, as messages despatched from Hong-Kong at 11 A. M. are received in London at 9.30. With the duplicate lines in working order, therefore, no anxiety need be felt about the maintenance of telegraphic communication with the Far East. The accommodation already provided must be amply sufficient for their requirements, and is not very likely to fill shareholders' pockets with extravagant dividends. We would, therefore, caution the public against a third scheme, which, we hear, is about to be proposed. It is a common remark that opposition, or rather competition, is good, because it protects the public by preventing monopoly. But this is a dictum which must be taken with several "grains of salt." According to our own observation, it generally turns out that two rival schemes, after competing with each other furiously and ruinously for a short time, become persuaded of the policy of amalgamation. Moreover, when a few enterprising men have labored for years, and taken the risk of laying submarine cables to India and China without Government aid, we think they are entitled to some consideration from the public, and there can be no doubt that our China messages are conveyed cheaper by lines that are practically in the hands of one management, such as the British Indian, the Extension, and China lines than by any other. There is one cable still required to connect Yokohama. At present, the submarine lines of the Great Northern Company only extend from Wladiwostok to Nagasaki, Shanghai and Hong-Kong. The traffic to Yokohama would not warrant the laying of a special cable either from Hong-Kong or Wladiwostok; it must, therefore, be laid between Nagasaki and Yokohama—a distance of about 600 miles. We understand that a land line is to be laid by the Japanese Government connecting these places; also Osaka, Hiogo, and places in the Straits of Simonosaki, which will be completed next year, the wire and all necessary apparatus having been sent out from England.—*London and China Telegraph.*

ACTION OF LATERAL ELECTRIC CURRENTS UPON THE PRINCIPAL CURRENT.

THE effect which an electric discharge produces by its inductive influence upon closed neighboring circuits, and the action which the lateral currents, thus created, exercise in their turn upon the principal current, constitute one of the most frequent annoyances in electrical experiments. Herr Reiss has lately investigated this reaction of the lateral currents upon the primary and also their reciprocal action, the one on the other. Experience has proved that this modification of the principal current affects the duration only of the electric movements, but not the quantity of the electricity displaced. In order to make this perfectly evident, the author made use of his electric thermometer, and found that the magnetic needle gave no indications other than such as would have been produced upon the electric spark by the elongation, more or less, of the circuit. On the enfeeblement of the lateral current by the introduction of greater and greater lengths of fine platinum wire, the author observed that the principal current gradually diminished from 100 (its initial value corresponding with the maximum conductibility of the secondary circuit) to 62, but ascended to 104 or thereabout, upon diminishing the intensity of the lateral current. When the circuit of the secondary current was broken, it was raised to 144.

Herr Reiss has also studied the case of two lateral currents, so disposed as to have an equal bearing upon the primary current, and has found that when the resistance of one of the secondary currents (at first very feeble) is gradually and continuously increased, the secondary current at first diminishes, afterwards increases, diminishes a second time, and finally increases; thus passing through two minima and two maxima successively. The primary current attains its greatest value at the moment of the first minimum of the secondary current, it then gradually diminishes, without changing its course, to the moment of the secondary minimum of the secondary current, and ends by becoming constant. In this manner (thanks to the intervention of the second lateral current), it appears that a *constant* primary current is produced by the influence of a *variable* secondary current, in a circuit in itself *invariable*.

From these experiments the author draws the following conclusions:

1. The reaction of the secondary current upon the primary discharge does not attain its maximum value when the current is at its greatest intensity, but when it has been notably enfeebled.

2. Two lateral currents of this same kind mutually weaken each other when they are in the same direction, and reinforce each other when they are in opposite directions.

THE NEW YORK GENERAL OFFICES.

THE NEW OPERATING ROOM.

As we begin this article the operators engaged at the Western Union Telegraph Company's General office, 145 Broadway, are like bees preparing to swarm. As one looks through their present hive, with its low ceiling and dingy walls, the side lights leaving half the room in comparative obscurity, the necessity of a change becomes painfully obvious. Yet, when first occupied, it was deemed a rare place for the operator's work. We were the first occupants of the rooms just beneath. In 1858 Gen. Lefferts rented the building for the use of the American Telegraph Company and its associate lines. The rooms beneath the present operating room were rented to us, in connection with space in the receiving and delivery departments for the service of the New York, Albany and Buffalo Telegraph Company. We believe they were long regarded as the pleasantest for the performance of duty in the whole country. They are surpassed now by many in elegance, and many more resemble them in the feeling of comfort which made it a home to those connected with it.

In the arrangement of the operating room of the American Telegraph Company, under the management of the able Superintendent, J. C. Hinchman, Esq., the plan of running the office wires over the office tables on miniature telegraphic poles was adopted. The office was on the same floor with the receivers. The multitude of wires traversing the room, festooning every operating table, gave the public an idea of the magnitude of the Company's business. It was an interesting sight and an excellent avertisement. The office at 145 Broadway became practically *the* Telegraph office of the city.

We took another plan. We had no public to provide for. We occupied premises necessarily private. So, with care and patience, we led the Western wires through concealed passages to two clock faces armed with switches, each of which did not exceed a foot in diameter. From these we led the wires, planting them with our own hands, along the grooved wash boards and beneath the floor, up the perforated legs of the operating tables to the magnets and keys. Not an inch of wire was visible. The arms of the clocks made all necessary changes and connections. All tampering with wires was prevented and unprovoked. The operating tables were in desk form, with an enclosure for the machinery having a piano front, which could be used to reduce the sound, as the operator might desire, and also preserve the machinery from undue exposure when not in use. To reduce the sounds of so many instruments the floor was covered with heavy matting, and, to add repose, the walls and ceiling were kalsomined with neutral tints and preserved absolutely plain.

But now, in increased proportions, and with greatly enhanced effect and comfort, a new and, in every respect, superb room is being prepared for occupancy. By the time this meets the reader's eye it will be in possession of a corps of 100 delighted men. The upper floor of the building, formerly occupied

Digitized by Google

by the janitor and batteries, have been converted into one large, spacious room 110 feet long by 30 wide. Along the northern side and eastern front 16 windows give a cheerful light. This is greatly enhanced by a spacious skylight inserted into the ceiling, extending from end to end of the room. The skylights are arranged to admit light without glare, and so that the whole air of the room can readily assume, without disturbing draughts, the purity of the external air. The apex of the skylight is about 15 feet from the floor. With a taste which we commend, the walls are preserved from doubtful decoration, and finished in simple neutral coloring.

Into this room, through a cupola on the roof, are introduced 231 WIRES. Of these there come

From the South	31	wires.
From the West, via Allentown and Erie roads	15	"
From the West and North, via Hudson R.R.,	10	"
By Harlem railroad	10	"
From the East	21	"
From Long Island, Sandy Hook, &c	3	"
From auxilliary N. Y. offices and branches, including 50 "loops"	141	"

All these wires are made to pass through a double bank of lightning arrestors around the cupola. These arrestors are connected with a quarter inch copper wire, terminating in massive ground plates in the earth.

THE SWITCH.

In the centre of the southern wall a handsomely partitioned receptacle is located for the switch which distributes the wires to their appointed desks. This receptacle is twelve feet long by three feet deep. A door at each end gives access to the entering wires and to the rear of the switch board, so that every connection is easily accessible. Two gas burners illuminate every part.

The wires from the cupola, led down to thumbscrews on a ledge two feet from the floor, are all carefully designated, and form a kind of organ key board, on which the voices of commerce whisper to each other throughout the continent. From this ledge the wires are led to

THE SWITCH BOARD.

This is the largest and most comprehensive of any in America. It measures twelve feet long by three feet wide, and has in its construction no less than

SIXTEEN THOUSAND DISTINCT PIECES.

The appearance of the switch board is exceedingly elegant. It stands beneath a canopy of black walnut, of neat finish, with cornice of symmetrical proportions. At the base it is surrounded by an elegant counter of black walnut, of about eighteen inches width, on which are placed the machinery used by the managers of circuits in holding correspondence with offices on the various wires in the prosecution of their duties.

The city wires, worked by the Ladies' Department, two stories below, are led under the main switch to one of smaller proportions on the west wall. This switch accommodates 50 wires, in addition to the necessary battery connections.

All the wires running from the switches to the instruments are of gutta percha covered copper wire, made up in cables of eight wires each, and carefully covered in tarred canvas. The local and main battery wires are clubbed in the same way, and all led beneath the floor to their points of connection. About six miles of copper wire are thus used.

Along the room, standing five feet apart, are 28 tables, made of black walnut and chestnut, six feet long by four wide. These are subdivided by glass frames, placed so as to divide the surface of the table in four equal parts or compartments, accommodating, without interference, four sets of machinery. Thus one table accomodates four operators, and, in the entire room there are places for an operating force of 108 men, exclusive of those engaged at the printing instruments. In the centre of each table is a neat gas fixture, with porcelain shade, giving the whole room an appearance of great neatness, appropriateness and elegance. In the centre of the room are arranged the repeaters, on tables similar to the operating tables, having all the latest improvements, and under the immediate eye of the circuit managers.

On the south wall, in rear of the switch, is a neat enclosure, surrounded by a continuous desk for the clerks who handle the messages. Along the front of the desk neat pockets are constructed for depositing the messages. These are formed of slips of plate glass, duly labeled, so that the contents of each are easily seen. Ten clerks are employed in this department. Their duty is to receive and distribute the messages from the pneumatic tubes, copy and number for delivery all incoming messages, and drop them to the delivery and city departments.

Connected with this department are two copying presses, run by steam power. These consist of three iron rollers, with one of rubber in the centre. Through these, which are continually in motion, are passed all messages for the general delivery or for city line distribution, as they come from the operating tables. A piece of moist paper, always ready, is placed upon the message to be copied; it is then grasped by the first roller, pressed by the second, and is quickly issued, ready for passage to the tubes by the third. Thus, every message is preserved.

Terminating on the wall in the rear of the clerk's desk are the pneumatic tubes, four in number, connecting with the Receiving department, Ladies' operating department, and Cable room. These tubes are supplied with air by a Baxter upright steam engine in the basement, and render the connection of the departments of service complete and immediate, messages passing to each with great promptness.

Six printing instruments are placed along the south wall, and are propelled by steam power from the same engine which operates the tubes and presses. Formerly these were operated, or kept in motion, by men called "grinders," using a crank, and working in rear of the instruments. Six men are thus dispensed with, and the speed rendered uniform and continuous. These printers turn out, sending and receiving, about 2,500 messages per day. The Morse machinery transmits, sent and received, an average of 14,000 messages per day. Total average per day, 16,500.

The room, thus perfectly provided, is warmed by hot water pipes, which traverse the entire room. No more comfortable, healthful, cheerful, or well appointed office can be found. It is under the management of Mr. A. S. Brown, a most practical, excellent and well informed gentleman, who maintains an admirable discipline, without separating himself from the esteem and confidence of those under him. His assistants are

Mr. A. S. Downer, Mr. Gerritt Smith,
Mr. D. R. Downer,

gentlemen too well known to require encomium from us.

The night force is under the management of Mr. Thos. Dolan, assisted by

Mr. W. K. Applebaugh and Mr. C. S. H. Small, all well known and respected by the craft.

The whole of the arrangements thus somewhat imperfectly stated, as well as the original proposal to devote the premises to the purpose now so happily consummated, are entirely due to Gen. Eckert, General Superintendent, whose executive ability and taste can be seen in every part of the work. He has been ably seconded by Mr. Bateman Cates, from Boston, to whom was assigned the supervision of all the mechanical part of the work, and who has proven himself a man of rare energy, thoroughness, and skill. We congratulate the staff on their new and beautiful apartment, and hope they may long live to enjoy it.

IN CONGRESS—BUYING THE TELEGRAPH LINES.

Mr. Chandler, of Michigan, offered a resolution to refer so much of the President's Message as relates to the telegraphic system of the United States to the Committee on Commerce, and argued in favor of the resolution. In his opinion, the time had come when the relations of the telegraphic system to the commerce of the country ought to receive the careful attention of Congress. If the telegraph was an instrument of commerce, then Congress had power over it under the provision authorizing it to regulate commerce, and he thought it was clear that it was to be regarded mainly as an instrument of commerce, because probably three-fourths of the messages sent by telegraph were on commercial business. He contrasted the cheapness of telegraphing in Europe with its expensiveness here, and said that one of the great advantages of the European system would be the breaking up of the oppressive monopoly known as the Associated Press. But while he thought the Government should control the telegraphic lines, he would not be willing to buy the existing lines at the prices that the companies would be likely to ask, because he understood that there was a much larger proportion of water than money in their stock, and he was opposed to paying high prices for water. He would, however, agree to pay the actual cost of constructing the lines, or even what it would cost to construct them now, but no more.

Mr. Hamlin, of Maine, remarked that the whole subject had already been very properly referred to the Committee on Post Offices and Post Roads. If the telegraph question was to be regarded as within the province of the Committee on Commerce because most of the messages sent were for commercial purposes, then the Post Office Department also would come within the domain of that committee, because most of the letters sent through the mails related to commercial business. The resolution was laid over.

NEW QUARTERS—REMOVAL OF THE WESTERN UNION TELEGRAPH OFFICE.

Our friends of the Western Union Telegraph office have just got fairly at work in their new establishment, on the northeast corner of Third and Olive streets, and it is probably one of the best appointed of its character in the West. The edifice is a four-story marble front, and is mostly occupied by the company.

On the first floor, leading to which are two entrances, are the receiving and delivery rooms, a room for messengers, &c. Everything is with close regard to commodiousness.

The second-story front rooms are devoted to the business and private offices of the superintendent.

On the fourth floor is a large operating room, leading to which are thirty wires, running in all directions. Here, the arrangements in every particular are admirable. An average of two thousand messages a day are received, not including the very lengthy press reports.

THE FORCE

of the St. Louis office numbers about ninety-four, and is ranked as follows:

Colonel R. C. Clowry, superintendent of lines in Missouri, Kansas, and portion of Illinois, Iowa, Nebraska and Colorado. Colonel Clowry has 346 offices in his district.

Isaac McMichael, supply agent and chief clerk.

E. H. Brown, manager St. Louis office.

J. C. Hanchett, chief operator, St. Louis office.

C. W. Hammond, assistant chief operator, St. Louis office.

John A. Hobbs and A. E. Haquette, receiving clerks.

Joseph Hollohan, delivery clerk.

Also, twenty-six operators, fifteen clerks, forty-three messenger and check boys, two line repairers, one battery man and one janitor.

C. H. Sumners, the company's electrician, laid the wires and connected them in the most perfect and artistic manner.

We congratulate Col. Clowry upon this change. *St. Louis Democrat.*

A PROPHECY.

I would like to place upon record this opinion: that if the "State to State" tariff be adopted under anything like the existing conditions, the experiment will, financially, be a failure. ***

To the Editor of the Journal of the Telegraph:

In the Journal of November 15 a new way of making up the tariff is hinted at as possibly to come into use. Any tariff which does not recognize distance must be unjust and discriminating, and such would that be. Now, there is a plan, by which the most perfect uniformity and precision can be reached, which, if adopted and adhered to, will, in a short time, compel the proper distribution of circuits, distributing centres, &c. Some system must be adopted and stuck to, in order to derive from it all its advantages; and if justice to both the public and the company can at once be secured by any plan, that plan is the one to be accepted. No revolutions in the business could affect the plan I have digested. The tariff from every office to every other office could be changed, in a general notice of a score or so of words, and not a single office make a mistake. No expense of any moment would attend the adoption, because the material of which it should consist is now in the possession of the company. The brick and stone are all at hand; you need but the mason and the architect.

In conclusion, I will say that it is useless to offer suggestions or plans, by the adoption of which the company would make money or save money, if that is to be the end of it.

If there are none whose duty it is to inquire into or practice anything new, I, for one, might as well cease to waste the hours I could spend in sleep.

In the present disintegrated state of the integral parts of this vast corporation, it is about as impossible to adopt a good plan as it would be, in a political convention, to pass a resolution where there was no president, vice-president, secretaries, committees, &c. We have no conventions of practical telegraphers, no place or time for the interchange of views, facts, experience, or anything else which might be of general interest and profit. *Must* it always so be?

If the company wish to see my plan, and will give it fair examination and mature deliberation, I will take pleasure in drawing it neatly and comprehensively. ***

NOTE.—Send on your plan. We promise it attention. What we want is a plan, not a complaint; not a prophesy of failure, but a project promising success.

GLAD OF IT.—Mr. Simeon E. Mayo is meeting with well-deserved fortune in Albany. Sim. is one of the best fellows in the world, and all of his old friends will rejoice at his promotion. The Albany *Times*, of Saturday, says:

"Mr. S. E. Mayo, General Ticket Agent of the Delaware and Hudson Canal Company, Susquehanna Railroad department, has been appointed to the like position on the Rensselaer and Saratoga Railroad, vice O. N. Crandell, of Troy."

(We are glad of it, too, and we know it to be deserved.—*Ed. Jour.*

ANNUAL ELECTION OF DIRECTORS OF THE INTERNATIONAL OCEAN TELEGRAPH COMPANY.

The annual election of Directors of the International Ocean (Cuba Cable) Telegraph Co., was held at the office of the Company in this city, Tuesday, December 12, 1871, and the following gentlemen were chosen for the ensuing year: Messrs. Henry K. Bull, M. L. Delafield, David H. Haight, Alexander Hamilton, Jr., Robert J. Livingston, Charles Knap, James T. Sanford, Wm. F. Smith, and E. S. Sanford.

At a meeting of the Directors, held on Wednesday, December 13, the following officers were unanimously elected: President, Gen. W. F. Smith; Vice-President, James T. Sanford; Secretary, Alex. Hamilton, Jr., and Thomas P. Bladen, Treasurer.

WASHINGTON, Dec. 19, 1871.

The President of the Western Union Telegraph Company was before the Committee on Ways and Means this morning, and made an argument in behalf of a proposed reduction on telegraph wire. No action was taken.

SAN FRANCISCO, Dec. 16, 1871.

A bill has been introduced in the California Legislature, and referred to the appropriate committee, giving to the Pacific Submarine Telegraph Company the right to construct lines and land cables for an interoceanic telegraph to China and Japan, either direct or by the way of the Hawaiian islands.

RELATION OF HEAT TO ELECTRICITY.

To the Editor of the Chemical News:

It is generally said that the heat produced by a current of electricity varies as the square of the current (with the same resistance). I have no doubt that this is true in the cases from which the rule has been deducted, namely, where the sources of the electricity have been the same.

The following experiment would tend to throw a doubt on the general truth of the rule where the electricity is derived from different sources:

I took two elements, one of zinc-platinum and the other of iron-carbon, with the same electrolyte. The current from the former was 87° on a tangent galvanometer, of the latter 85; consequently the heating effects of the two currents ought to have been as the squares of the tangents of those angles, or about as 36 to 13; yet, on trial, I found the former would keep only about 1¾ inches of a platinum wire red hot, whilst the latter would keep 2¼ inches of the same wire red; also in deflagrating different gauges of iron wire, I found that the latter would deflagrate like tow wire, which the former would keep scarcely red hot. The sparks from the latter were also much more brilliant than from the former, emitting bright flashes and scintillations when a copper wire was rubbed along the rough edge of a rusty piece of iron.

The subject is worth investigating, and I venture, through your columns, to call the attention of scientific men to the point.

I am, &c., H. HIGHTON.

INTERNATIONAL TELEGRAPHIC CONFERENCE.—Mr. A. E. Chambre, one of the principal officials of the telegraph department of the General Post Office, has been appointed delegate or representative for the British Postal Telegraph Department at the International Telegraph Conference now being held at Rome. All the states of Europe will be represented at the conference, England taking a part therein for the first time since the telegraphic system of the kingdom has been acquired by the state.

ELECTRIC BATTERY OF D. M. COOK.

We learn that Mr. Cook is about to bring this invaluable invention before the world, and we anticipate wonderful results from it, as it must work out an entire revolution in the history of electric and calcium lights. We understand that twenty-six cups, under Mr. Cook's arrangement, yield a light equal to four hundred lamps, at an expense not exceeding ten cents per hour, greater results being obtained at much less expense in proportion to the amount of light.

The principle of this battery is entirely new, it having been overlooked by other electricians. It is very simple in its construction, composed of only a new combination of the old materials used in other experiments. It is composed of seven or more simple elements united as one, and their electric quantities read about as 1, 3, 6, 12, 24, 48, 96, for one compound element, while two of these, united as one, constitute a quantity battery two hundred times that of a "Grove," and one hundred times its endurance, consuming but one hundredth part of the material in doing the same amount of work. This renders it a source of light for public purposes much more economical than gas.

And we hail with pleasure the day when our cities and towns can be illuminated with this sparkling light. One thing is certain, that this new element opens the field for the successful application of electricity that heretofore could not be made, since the chances of success by this are more than a hundred to one over that of the old element.

We trust Mr. Cook will meet with the encouragement from all lovers of the sciences in the domonstration of this new principle of electricity.—*Exchange.*

TELEGRAPHY IN FRENCH RIVERS.—Workmen have taken up two telegraphic cables laid down in the Seine between Rouen and Paris, shortly before the seige of Paris, to enable the capital, if invested, to communicate with the provinces. The last portion of the wire, between Carflaus and Paris, was completed two days since, and the cables have been sent to Toulon to be repaired.—*Engineering.*

THE GREEK ARCHIPELAGO CABLES.—The Malta correspondent of the *Times* writes under date of Valetta, Nov. 11th: The submarine line of telegraph between Corfu and Zante was completed in the early part of November, but will not be opened till the completion of the land line between Point St. Gordi and the town of Corfu—a distance of thirty miles—which will be ready to-morrow, when the new and rapid route to the Ionian Islands, the mainland of Greece, and the most important islands of the Greek Archipelego, as well as Candia, will be available.

DIED.—At Plymouth, Ind., December 7, 1871, Robert Poe Fulton, in the thirtieth year of his age. Mr. F. has been for several years past Agent of the P. Ft. W. & C. R. W., at Plymouth, Ind. He posse sed fine business qualifications, secured the entire confidence of employers, and of all others with whom he had occasion to transact business.

Mr. Fulton was an operator of many years standing, mostly on my lines, although at one time a manager or chief operator of the Old United States Lines in Philadelphia. While working for me he was promoted to the Station Agency at Plymouth (some two or three years ago), since which time he has handled the key only in emergencies, which he ever stood ready to do. At the time of the "strike," he volunteered his services, doing double work, almost, in addition to his duties as Agent. He was one of the "old guard" which rallied around the company so nobly in its extremity, and saved it from defeat. He was a true man, and has gone to his reward.

O. H. BOOTH.

INTERPRETING RULES.

To the Editor of the Journal of the Telegraph:

A gentleman telegraphed West to the house for which he was traveling, asking instructions for his future action. After waiting all day for his answer, he called at 7 or 8 o'clock in the evening, and was informed that his message was received, but being *red*, could not be delivered till morning. The gentleman offered the unpaid half tariff, stating that he wished to go West that evening, but the manager regarding the rule as inflexible, would not deliver the message, and the gentleman remained over night on expense, with loss of time, which, considering the season, was valuable to him, to receive his message in the morning.

I should have helped that man off the evening before by giving him his message, and though I had broken one of the Company's rules, I should have made a friend for the Company, and saved it from the abuse to which I, as well as numerous others, listened in my office the next day.

NOTE.—We cannot agree with X. The house for whom this agent served sent a "red" message to save a paltry sum of money, and it cost them a night's expenses at a hotel, and the detention of their agent. It served them right. When a man chooses to ride on the top of a coach so as to go for half price, he must take his chance of the rain. The agent's cursing was ill directed. He ought to have, barring the cursing, vented his wrath on his stingy principals.

WHAT BOOK SHALL I BUY?

SHAWNEE, KANS., Dec. 12, 1871.

To the Editor of the Journal of the Telegraph:

Having noticed that you, in almost if not quite every issue of your valuable paper, answer questions asked you by correspondents, I therefore take the liberty of asking one, hoping you will consider it worthy of an answer. "What is the best work treating on the subject of the telegraph and electricity, and where can it be procured?" I sometimes have questions put to me regarding my business which I cannot answer correctly, thus making me ashamed of knowing so little about my own profession. Situated as I am, at a small station, I have no advantages for gaining the knowledge I seek. By answering the above question you will confer a *great* favor on a learner of the art.

I remain, my dear sir, very truly yours,

ALF. S. FIELDING.

Reply.—For general knowledge on all practical subjects connected with the telegraph and its duties, we deem Mr. "POPES' MODERN PRACTICE OF THE TELEGRAPH" most suited for our correspondent. Its cost is $2, and on receipt of that amount we will see that it is sent to any who desire it. For Telegraphic history, and statistics, Mr. Prescott's Theory and Practice of the Telegraph is the most ample. Price, $2.50.

FORT DODGE, IOWA, Dec. 4, 1871.

To the Editor of the Journal of the Telegraph:

I am unable to explain the following. Will you be so kind as to enlighten us on the subject:

During a heavy snow storm December 3, this wire was charged with heavy electric discharges, enabling us to work, as the following will show: I cut in, and could hear nothing. I put G. W. on West and heard Eastern office calling me; could not break him, and took G. W. off, and said I was under the impression he heard me; if so, make dots and answer. I then put G. W. on West and heard him answering me, and in that way we were enabled to do a little business. I could not hear him unless I put G. W. on, or him me unless I took it off. Eastern operator worked with back stroke of key and relay. The circuit was complete through. Please give us an explanation; and is there any possible way to work a line under such circumstances? Operator East received from me with key open.

A STUDENT.

Answer.—Electrical snow currents are not uncommon. Without knowing many necessary details, we answer:

1. The East could not receive from you with a ground on, because you not only cut off your West battery thereby, but reduced, supposing yours to be an intermediate office, the storm or snow current by decreasing the length of exposed wire and manipulating where you had no command of any curcurrent.

2. You could not receive from the East without a ground, because, by grounding, you gave the East battery less of the snow current to resist, the polarity of your battery being probably contrary to that of the storm. By removing the ground you rendered the current from both storm and battery nil, by their reverse polarity and proximately equal power.

3. The peculiar mode of sending and receiving, all except the open key, would be commonly explainable by an escape, more or less heavy, between the stations. The reception on an open key shows the high tension of the storm current which leaped the open space at the key.

RED MESSAGES.

To the Editor of the Journal of the Telegraph:

A question for your next issue, with answer:

In the case of the receipt of a "red" message, Saturday evening, at an office not required to be kept open Sundays, when should the message be delivered? Is not the suspension of business between the office hours of Saturday and Monday the same as that between any other two days?

B.

Answer.—Monday morning.

A GOOD THING TO GET.

CARLISLE, PA., Dec. 13, 1871.

To the Editor of the Journal of the Telegraph:

By to-morrow's (Thursday's) express I send you a turkey (alive) for Christmas. Please accept the same, with best wishes of the sender, and hoping you may have a happy Christmas and many returns of the same.

Yours truly,

J. CAMPBELL.

To the Editor of the Journal of the Telegraph:

An incipient operator writes that he has learned all the letters and would like to borrow a machine that makes the dots, as the one he is using "only makes the dashes." Can you assist him?

Yours ,&c., ——

No. We are afraid he is a *dashing* fellow.

GREAT complaints are made of the disorganized state of the public departments in Turkey, especially that of the telegraphs and posts.

FALMOUTH, GIBRALTAR, and MALTA TELEGRAPH (LIMITED).—The ordinary general meeting of this company was held at the City Terminus Hotel, Cannon street. The report stated that the new alternative cable between Lisbon and Gibraltar was completed on the 9th October, and that the original direct cable between the same points had been thoroughly repaired and laid in a safer position. The company now possess two lines of communication between those important stations, one of the lines being used for local and the other for through traffic. The section of the Australian Company's line from Java to Australia would shortly be completed, thus insuring a further increase of traffic.

THE GOVERNMENT TELEGRAPH SCHEME.

The President, in his Annual Message, and the Postmaster-General, in his Annual Report, recommend to Congress the serious consideration of the proposition, first suggested a few years ago, that the Government shall undertake the conduct and management of all the telegraph lines of the United States. This is a measure of such magnitude and importance as to demand more consideration than it is likely to receive in the debates of Congress, and to be discussed from a higher standpoint than that of mere partisan utility. The arguments seem to us to be convincingly against the project. The telegraph system of the United States is a private enterprise. It has grown to its present condition of comparative perfection as a result of individual energy and management, obeying in its development the law of demand and supply, and progressing as rapidly as the judicious investment of capital would warrant. If the Government may step in, under any hidden power in the Constitution to do anything and everything, and purchase all the telegraph lines of the United States, why may it not also purchase the railroad lines? And if Mr. Sumner's "sleeping giant in the Constitution" may wake from his drowsiness to grasp the telegraphs and railroads, why may he not also secure the steamboat lines on the great rivers before he lies down to take another nap? And if all these, why not the ferries, the bridges, and turnpike roads? And when he has safely bestowed all the lines and vehicles of travel under his arm, why not, for the comfort and protection of those who entrust themselves to his care, take charge of the hotels and boarding-houses? In short, where is governmental interference with such enterprises, when once begun, to stop? The line must be drawn somewhere, and we prefer that it shall remain where the necessities of the country have placed it up to the present time.

But we are told that the telegraph is a legitimate branch of the Post Office Department, and that, as the latter is under Government control, so should the former be. This is a better reason why both Post Office and telegraph should be conducted as private enterprises, than that both should be in the hands of the Government. It is quite possible to conceive of conditions under which the Post Office would be better managed as an individual enterprise than as a branch of the National Government. It is the latter by use and consent, rather than by inherent right or duty. On the one hand, there is no more reason why the Government should be compelled to carry a letter from John Smith in New York to James Brown in St. Louis, than that it should be compelled to carry a box of dry goods from and to the same parties; and, on the other hand, the Government has no more right to monopolize the carrying of the letters than it has to monopolize the carrying of the dry goods. The National Post Office system, when established, was in the nature of a burden assumed by the Federal Government for the benefit of its citizens, not of a business in which it was in duty bound to engage. The country was thinly settled and not easily traversed, and as the Government had to keep up communication with the remotest parts, the Federal mail service was established as a benefit to the people, without much additional cost to the nation. The reasons which operated in favor of the postal service are not applicable to the telegraph. The Post Office is a necessity of civilization; the telegraph is a luxury, and the Federal Government cannot afford to foster all the fine results of our advancing civilization.

If the proposition is wrong in theory, it would be still more wrong in practice. We have not the least sympathy for, or interest in, the great monopoly which now controls the telegraphic wires of this country. But we prefer to bear the ills we have than fly to others of which we know too much. Law and competition may do something to relieve us from the oppressions of the existing system; Government control would give no promise of individual relief, while increasing the sum of national trusts and national responsibilities. The fact that it would add another "bureau" or "department" to the long list of useless ones already established, is an evil which it would take a large promise of public good to neutralize. First, we would have the Telegraphic Bureau, with its chief and its clerks, crowded with men who could not discriminate between the ticking of an instrument and the ticking of a clock; attached to this would be thirty thousand operators, suddenly resolved into political integrals, and removable for political cause. The "bureau" would soon want to be a department, and its chief a member of the Cabinet. And so on to the end of the chapter—evil, and that continually.

It is urged, as one reason for the adoption of this system, that it has been successfully tried in England. We doubt both premise and conclusion. We are by no means assured of its success in England, and even if that were established, we would not be at liberty to deduce success in this country from it. There are essentials of territory, population, and business, which render any just comparison impossible. To these we shall refer again in the discussion of this important subject. The proposition now before Congress must stand or fall according to its merits and adaptabilities to the needs of American civilization and the genius of the American Government, and totally independent of examples, whether of success or failure, in other countries.

For the present, the most that can be done is to call the attention of the people to it, in the hope of getting a fair investigation and an honest verdict. It has three important bearings, in each of which it must be critically examined: first, as to the constitutional right of the Government; second, as to the precedent it would establish; and third, as to the benefits that would accrue to the people from the proposed change of management and ownership. Unless there is a concurrent and affirmative answer to the inquiries which these propositions suggest, Congress had better let the telegraph system of the country remain where it is.—*From the Missouri Democrat (St. Louis), Dec. 8, 1871.*

RAILROAD ITEMS.

Cairo and St. Louis.—This road, running through the river counties of Illinois, gauge three feet, is the pioneer narrow gauge from St. Louis. Construction is progressing rapidly. Twelve miles are ready for the superstructure. Cars will run to Sparta, Randolph County—fifty miles from St. Louis—by the first of May, and to Murphysboro, Jackson County, thirty miles further, the first of July. The road will be completed its whole length by next fall.

Railroad Extension in Michigan.—The Upper Peninsula of Michigan has but 115 miles of railroad in operation, or one mile to every 196 square miles. The upper half of the Lower Peninsula, seven years ago, had not one mile of railroad in operation, and up to January, 1870, there were but little over 100 miles of road in operation, or one mile of road in every 170 square miles. To-day, there are over 250 miles of road in operation, or one mile of road to every 68 square miles; besides, there are projected and now being constructed 300 miles of road, to be completed in 1872, when this district will have 550 miles of road in operation, or one mile to every 30 square miles.

The people along the line of the Decatur, Sullivan and Mattoon Railroad had a grand celebration the other day, on the completion of the road, which is an extension of the Chicago and Illinois Southern, from Mattoon through Moultrie into Macon county, to a point within ten miles of Decatur.

Chicago, Danville and Vincennes.—This important line is now opened to Danville, and its connecting line from Danville to Terre Haute is also completed—forming, with the Southern connection of the latter, a new and direct through line from Chicago to Evansville, as soon as running arrangements can be perfected.

INSTRUMENTS USED IN STORM SIGNAL SERVICE.

Besides the common mercurial thermometer, the Signal Service makes use of two others, namely, the maximum and the minimum thermometer. The maximum thermometer consists of a common mercurial thermometer, stationed in a horizontal position, inside the tube of which is placed a steel index; this index is pushed forward by the mercury, as the temperature rises; but when the temperature falls, and the mercury recedes, the index remains stationary, thus registering the highest temperature. The minimum thermometer is a common thermometer in which spirit is substituted for mercury; a steel index is inserted; when the temperature falls the index is dragged with the spirit; increase of temperature and the consequent rising of the spirit does not affect the index, which still remains at the lowest point, thus registering the lowest temperature.

To measure the velocity of the wind an hemispherical cup anemometer is used. It consists of four hemispherical cups placed at the extremities of two horizontal rods which cross each other at right angles. The cups revolve with the wind, and the rods, or arms, are of such a length that five hundred revolutions is equivalent to a mile of wind. These revolutions are registered by a system of index wheels, set in motion by an endless screw on the upright which supports the rods. The force of the wind is ascertained by a tube, bent like a syphon, called a wind guage. It is one-half filled with water, and its open end always faces the wind, the instrument being adjusted on a pivot. The force of the wind drives the water up the opposite leg of the instrument, which is graduated.

By putting a chemical solution in the water and pieces of prepared paper along the side of the graduated leg, it may be made to register the greatest force which the wind attains.

The rain gauge consists of a copper cylinder, its upper end closed by a funnel to prevent evaporation. The rain is collected in a second vessel placed inside the cylinder, and thence measured. The relative amount of vapor in the air is measured by the hygrometer. Two mercurial thermometers are placed side by side; one, a common thermometer, is called the dry bulb thermometer, the other has its bulb covered with muslin, from which pass threads of darning cotton into a small vessel containing rain water; this is called the wet bulb thermometer. The water rising by capillary attraction keeps the bulb constantly wet. When the air is dry, evaporation from the muslin is rapid; and, on account of heat lost by evaporation, the wet bulb thermometer indicates a lower temperature than the dry one. When the air is damp, the evaporation is slower, and the difference between the two thermometers is smaller. When the air is completely saturated with moisture, the evaporation ceases entirely, and the two thermometers are equal. *Scien. American,*

Address—

JAMES D. REID, Editor,
Executive Rooms, Western Union Tel. Co.,
145 Broadway, New York.

NEW YORK, JANUARY 1, 1872.

1872.

Kind greeting to all. We grasp every hand as the young year opens its expectant eyes, and wish that it may be a child of joy to each one of you. There are, we notice, marks of tears on some faces, from past suffering, from undeserved neglect. There are some downcast faces, revealing disappointed, discontented, and anxious hearts. But let all these be changed to-day. Time is not alone a destroyer of good. He comes with a smooth hand to remove the furrows and inspire hope. A true heart ever wears a crown, although the outside ermine be gone. They alone are to be pitied who come upon the new year with records of a faithless past, and with no radiance upon their hearts to shine for the sake of others. That life is the richest which is the readiest for sacrifice, and 1872 has most for him who desires most for others. Such is our first thought, as we inhale the young breath of the new-born year.

The year now opened is to be one of unwonted progress. The advance of the past year has been prodigious. The year to come will not be less so. In the administration of the telegraph, especially, will this be felt. It may not attract notice. No bulletins may note the progress. But the head which felt the grandness of a bond which united two oceans, now looks on the globe as on a rope walk. The grasp is wider, easier, more intelligent, and has more of the future in it. Like a tree, the processes of whose structure thickens the trunk as the head rises starward, the telegraphic administration is not only extending, but growing in the vitality and felicitousness of its detail. The public mind proves this. It accepts the telegraphic service of to-day with a hundred fold heartier assent than a year ago. This feeling will strengthen. Another year will make the proposal of a governmental telegraph an absurdity. The keen instinct which, from the mere motives of self-interest, builds for itself, will build better for all.

Let all enter the opening year with a manly design to do his best. The business has inspiration in it. Let this be joined to a higher intelligence, and a kinder use of power, wherever held. In nothing is there such inter-dependence. The boy that, on this sharp morning, trots through the crowd with his message, is as necessary as the executive officer who arranges the pay roll and directs the service.

No INVENTION, short of the Telegraph itself, has been so successful, so profoundly useful, as the Fire Alarm arrangements now in so extensive use in our large cities. And there seems, also, as if only one system gave complete satisfaction in its employment. Its rapid introduction and widening use sufficiently attest this. And Mr. Gamewell deserves success. He has given the system which bears his name the most conscientious and scrutinizing care. Every complexity has been removed. It is utterly simple. A child can give the alarm. It is now so distributed in large cities that the fire engine seems to stand by the side of every home, ready for work. Of this we will speak more fully hereafter. No city should be without it. It is one of the necessities of our civilization.

AS AN indication of the gradual dawning of an era of more perfect sympathy between the departments of telegraphic labor we take especial pleasure in notifying the members of the Telegraphers' Insurance Association that, on his own voluntary application, Mr. Orton, President of the Western Union Telegraph Company, is now a member. His note to us was as follows:

EXECUTIVE OFFICE WESTERN UNION TEL. CO.,
NEW YORK, December 23, 1871.

Dear Sir: I desire to testify my interest in the Telegraphers' Life Insurance Association by applying, as I do hereby, to be admitted to membership.

Very respectfully, WILLIAM ORTON.

This is an important act. It must touch many hearts. It admits the common heritage of death and sympathy with the provisions which relieve its darkness. In this the President now stands beside the humblest operator. It goes further. It ensures active executive sympathy which will make itself felt at every favorable opportunity.

WE have equal pleasure in announcing that among the most recent applications are

George H. Mumford, Vice-President,

R. H. Rochester, Treasurer.

In another issue we hope to be able to publish some gratifying facts which will stimulate the friends of the Association to an increased regard for it, and indicate the pleasant and successful future which seems to be in store for it and them.

IT is characteristic of the immense impetus given to telegraphic operations during the past year, that already there is a strong opposition between London and China. Messages can be sent either by the Persian Gulf and Southern India or by way of Russia. The former is essentially a cable route, the land line being comparatively short and occasional. The latter comprises 6,000 miles of land lines, through vast regions of comparative waste. The tariff by the latter is about fifty per cent. less than the former, and, as an English editor remarks, that, perhaps, properly represents their comparative value. The land lines must, of necessity, be liable to frequent interruption as compared to a cable route. Still the cables in China seem to be somewhat uncertain. Reports of breaks in them have been coming somewhat frequently. Not satisfied with this state of contest, a third line is hinted at as under consideration. These opposing lines are often the result of collusion with the cable makers, who take a large amount of stock and thus induce capital to enter.

NEW CABLE PROJECTS.

The European and South American Telegraph Company (Limited) was introduced in London, December 5th.

Capital, £1,250,000, in 62,000 shares of £20 each.

The cable is to be in four sections.

1. Portugal to Madeira.
2. Madeira to Cape de Verde Islands.
3. Cape de Verde Islands to St. Louis, Africa.
4. St. Louis to Brazil.

The rights granted are exclusive for 60 years.

Connections will be with all Brazil, Uruguay, Chili, by contract with existing lines. Tariff to South America, £3 for 20 words, and will compete for West India business.

Three parties have claimed the Brazilian grant.

1. The India Rubber Company, who base their claim under an agreement with Balestrini, the original grantee.

2. The Telegraph Construction and Maintenance Company claim a grant in 1869. The Brazilian Minister says that his Government is free to grant this concession as soon as the claims of the original grantee, Balestrini, are settled.

3. The Chairman of the European and South American Telegraph Company says that the grant they act under was given to Balestrini in 1866; that the grant was subsequently sold for a large sum to a society of seven persons, who, by a majority vote, transfer it to the E. and S. A. Telegraph Company. Balestrini objected to this, sued, and was defeated. He then transferred his rights to the India R. G. Telegraph Works Company, who formed a company now defunct. The Court of Appeals declared Balestrini's transfer void.

The Telegraph Construction and Maintenance Company claim the grant, on the ground that they have a concession which takes effect when the grant of 1866 expires; but as the European and S. A. Telegraph Company appear in earnest, and their stock is at a premium of 1¼, and all taken, nothing more will likely be heard of the claim. Hooper's Manufacturing Company have the contract for the cable. Cost, £1,150,000. The Board is largely composed of gentlemen connected with the Submarine Telegraph Company. Whatever success may attend this new enterprise will be wholly due to the failure of the laying of the West India cables. A fine field seems lost.

Offices which have not received their State Tariff sheet should at once apply to their Superintendent therefor.

HANDSOME PRESENT.—The friends of Mr. A. B. Waite, foreman of construction in the seventh district of the eastern division of the Western Union Telegraph Company, called on Mr. Waite, at his residence on East Washington street, and presented him with a valuable Grossman watch and a beautiful chain. The watch bore the following inscription: "A. B. Waite, from his telegraphic friends, Dec. 25, 1871."

Bound copies of the JOURNAL, volumes 3 and 4, are now ready. Price, each, $2.

THE TELEGRAPHERS' INSURANCE.

As a New Year's gift to the members of the Telegraphers' Mutual Life Insurance Association, we are extremely happy in being able to present the following letter from Mr. Orton. This is a quicker response to the feeling we felt sure his connection with the Association would evoke than we had any right to expect. We now bespeak for it a careful reading.

MR. ORTON'S LETTER.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, Dec. 28, 1871.

J. D. REID, ESQ.

Dear Sir: Referring to the conversation had with you a few days ago, and to the suggestion which I then made concerning the Telegraphers' Life Insurance Association, I now have to say:

That at the meeting of the Executive Committee yesterday my proposition was approved, and I was authorized to carry it into effect for and during the year 1872.

In order that the matter may be fairly understood I repeat the proposition:

First. The Association will not pay to the family of any deceased member more than one thousand dollars.

Second. The Company will add to the payment made by the Association one hundred dollars in each case of the death of a member of the Association who is at the time in our employ.

Third. The funds of the Association may be deposited with the Treasurer of this Company, who will allow interest thereon at the rate of six per cent. per annum.

I earnestly hope that this action on the part of the Company will result in stimulating a more active interest in the success of an Association which is capable of doing a vast deal of good at a comparatively nominal cost to each member. Although the stipulation on the part of the Company is limited to a year, I am confident that at the expiration of that time it will be cheerfully extended.

Very respectfully,

WILLIAM ORTON, President.

Three things will be noticed in this letter:

1. The prompt action of the Executive Committee in accepting the President's proposition. It is an assurance of sympathy.

2. The bonus is offered on condition that death payments be limited to one thousand dollars. We favor this limitation, as do the other members of the Insurance Executive. As the membership enlarges, as it must under the stimulus of this generous action, the average of deaths must increase in somewhat corresponding ratio; but by limiting the payment at death, a fund will accumulate, from which an occasional assessment will be paid without calling on the members. Thus, should the list swell to 3,000 members, as it may and should, and remittances be promptly and faithfully made, *three* deaths will be provided for by one assessment. We think this will commend itself to general approval.

3. It will be seen that interest at the rate of six per cent. per annum is to be allowed for deposits. This is a decided advance and advantage, and when parties send payments for coming assessments, they will have the satisfaction that they are at the same time strengthening the Association.

Thus the new year opens auspiciously. We congratulate you on this new accession to the attractiveness of your work, on all you have done, and on all you are likely to do. It is true that all this means many added hours of labor to us and Mr. Applebaugh, but we will do it cheerfully as long as we can. Let the bonds of the Association be widened, and the kindness which springs from its fellowship be made to permeate the whole service. Thus will it perform a double work. It will assuage grief, it will lighten up the darkness which death brings, and it will also elevate the hearts of the living to a nobler life.

IN our last nnmber we published a few lines, clipped from the letter of the Washington correspondent of the New York *Herald*, stating that when the matter of the Postal Telegraph system recommended by the Postmaster-General was brought up in the House, it was referred to a special committee. We thought our source of information reliable, and so used it without further thought, and in a perfunctory way sent it to press. The facts were otherwise. The subject was referred to the Committee on Appropriations. So far as the Postal Telegraph is concerned it will be a committee of non-appropriation. Public sentiment is unmistakably against it.

WE acknowledge the reception of a splendid specimen of a Pennsylvania turkey—alive—for our Christmas dinner, sent by our old friend, John Campbell, of Carlisle, Pa. He and his brother Jacob, who is now virtually in charge of the Mexican telegraphs, having built nearly all of them, were our own companions in labor quarter of a century ago. The kindly feeling existing between us then remains unbroken. Blessed is the labor which binds the hearts of the laborers together, and is productive of living turkeys.

WE have also great pleasure in acknowledging the receipt, on Christmas morning, of a handsomely framed photograph of three old and dear friends. It was headed,

PEOPLE'S TELEGRAPH LINE, CHRISTMAS, 1852.

And underneath the likenesses of

John Van Horn, now General Superintendent,

James Compton, now Sup't. Jackson, Miss.,

D. Flanery, now Sup't. New Orleans, La.,

were the words,

TUSCUMBIA, ALA., CANTON, MISS., JACKSON, MISS.

J. D. R., Sup't.

It is very gratifying to be thus remembered by the gallant men who served us in the days gone past. There are no truer men to-day; none on whom a company can more fearlessly rely. Kind of heart, persistent in labor, with an integrity which no temptation can shake, we look on their faces, feel honored by their remembrance, and say, "God bless you."

M. LOUIS, founder of the journal "*Des Postes et des Telegraphes*," has published a new mode of ærial signals for maratime and military uses, based on the Morse system. This is, simply, by the use of baloons, one dark, the other light, which may be placed in such relations to each other that one may represent a dot, and the other a dash. Or, they may represent figures, and these be the key to words known only to the parties in communication. For example, one white baloon would represent the figure 1; one dark and one white, the figure 3; one dark, the figure 2, and so on. By the use of a table, as below, two figures being signalled, one from the upper line and one from the side column, where these intersect, the letter would be indicated. Thus, 11 would be a, 22 g, 23 m, 32 h, &c.

Examples.

	1	2	3	4	5
1	a	f	k	p	u

This table, of course, is capable of infinite changes.

THE NEW STATE TARIFF.

This newly arranged Tariff, which gives a single rate for every office in a State, with every office in any other State, goes into effect January 1, 1872.

The exceptions are as follows:

1. **No rate shall exceed those on Special Sheet A.**
2. **In States marked with a * the existing Tariff shall continue in force, but shall not exceed the rate in the State Tariff Sheet.**

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
January 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since Dec. 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

THE POSTAL TELEGRAPH.

Mr. Creswell, in his argument for the consolidation of the Telegraph system with the Post-Office, relies chiefly upon the experience of Great Britain, where, if his statements are correct, the Government has derived from its telegraphs, in the first year of the new system, a net revenue of more than three millions of dollars. If that were true, it would be no rule for us. Great Britain is a compact little island, where the lines are short and the ratio of messages to the whole population is very high. The British figures quoted by Mr. Creswell represent an annual transmission of about 13,000,000 messages, exclusive of the voluminous news dispatches to the press; while, in the United States, two years ago, with a population nearly one-third greater than that of the United Kingdom, the whole number of messages was about the same. Considering the enormous length of our lines, and our vast area of agricultural country in which there cannot be a very general popular use of the telegraph, it is evident that the system would be far more expensive in America than it is Europe.

But Mr. Creswell's statement of the pecuniary result of the consolidation in England is not correct. He quotes from "the official report of Honorable (he is not an honorable) George Chetwynd, receiver and accountant-general of the British office," to show the receipts and expenditures for the fiscal year ending March 31, 1871, and gives the following figures: Gross receipts, £971,215 13s. 11½d.; payments out, £273,281 17s. 3½d; net produce, £697,933 16s. 8d., or $3,391,954 38. Now we have before us the official statement of Mr. Chetwynd of the income and expenditure of the postal telegraphs, not for the fiscal year, but for the 14 months ending March 31, 1871, and an accompanying report to the Chancellor of the Exchequer, by Mr. Frank Ives Scudamore, Secretary to the Post-Office; and both these documents tell a very different story from the one with which Mr. Creswell favors us. It appears, from Mr. Chetwynd's report, that the gross receipts of the 14 months were £1,068,585, from which must be deducted £270,005, paid to submarine telegraph companies in respect of collections on their behalf, and allowed to postmasters and others for delivery of messages and refunded message money. This is evidently the item of "payments out," which Mr. Creswell committed the extraordinary blunder of supposing to be the gross expenditure; and the residuary £798,580 represents not the net profit but the gross revenue! Mr. Creswell, in short, has not got at the expenditure at all.

What the cost of working the lines has been is not clear from the British reports. The whole outlay, exclusive of payments to the companies whose lines were purchased, amounted to no less than £1,397,389; but a part of this is fairly chargeable to capital account. Mr. Chetwynd estimates the actual working expenses at £470,495, and charges the remainder, £926,894, to capital expenditure. But this is a deceptive classification. Under capital expenditure he places not only the cost of extensions, amounting, as well as we can make it out, to £178,933, but all manner of outlay upon the plant (such as the very important item of maintenance and repair, for which the Western Union Company, in America, spends a million dollars a year), £177,094 for "engineering salaries, wages, traveling, and other expenses," which we should certainly charge to current expenditure, and the money spent for "preliminery instruction" and "bonuses to learners." If we refer these, and various other items, to the heads under which they really belong, we shall find the expense of the British Postal Telegraph system, during 14 months, to be £1,218,456, and the income £798,580, leaving a deficiency of £419,876. That would be equivalent to a loss of £1,749,091 a year (in gold), instead of the magnificent "net produce" of $3,391,954 discovered by Mr. Creswell. What confidence can we place in our Postmaster-General's reasoning when he has erred so egregiously respecting his facts?—*N. Y. Tribune, Dec.* 18.

To the Editor of the Journal of the Telegraph:

In case a party desires a despatch repeated, and wishes the repeated copy delivered to him, can we, under the rules, comply with his request? An answer in your valuable journal would greatly oblige,

Very respectfully, yours, ENQUIRER.

Answer.—According to existing rules, no.

THE report of the China Submarine Telegraph Company, presented on the 22d ult., states that from the opening of the line in June last the gross receipts up to the 4th of November have amounted to £26,895, and the estimated expenses to £6,550, and that the directors therefore anticipate they will be able to the 1st of January to declare an *interim* dividend of 6 per cent. per annum for the half-year terminating on that date.

THE report of the Falmouth, Gibraltar, and Malta Telegraph Company (Limited), presented on the 23d ult., recommends a dividend for the half-year at the rate of 7 per cent. per annum, which will absorb £23,576, and leave £8,897 to be carried to reserve.

THE report of the British Indian Submarine Telegraph Company (Limited), presented on the 24th ult., shows an available total of £44,823, and recommends a dividend for the half-year of 6s. per share, which will absorb £35,625, and with £1,578 balance from the last account, leave £10,077 to be carried forward.

INDIAN TELEGRAPHS.—The Supreme Government is said to have sanctioned a revised scheme for a patrolling and maintaining establishment for the whole of the Telegraphic Department in India.

M. PIERRET, formerly Inspector-General of the French Imperial telegraphs, is now appointed Director of their administration.

WE thank J. P. Dinsmore for a package of Carter's ink and mucilage. The ink makes editorial work a delight. The mucilage is dangerous to sit on, and we do not recommend it for that purpose. It sticks badly.

A SELF-CLOSING key is noticed and illustrated in the *Scientific American*, patented by Jeremiah F. O'Sullivan and Philip W. O'Sullivan, of Jackson, Miss. We have had bushels of such sent to us, all similar, yet different. They are all worthless for common use. A good switch is the best. We prefer the Caton form.

MR. JOHN POWER, operator W. U. Tel. Co., Canal street and Broadway, died, after a brief illness, December 13. He was a young man much liked and respected. In his sickness he was kindly cared for by Mr. Mitchell, manager, and who, after death, obtained a generous subscription from the operators, and saw him decently and appropriately buried. They "laid him down tenderly."

THE *Easton, Pa., Free Press* says of Miss Kate Denny, Manager W. Union Office there: "We bear cheerful testimony to the prompt and satisfactory manner in which the business of the office is conducted. Miss Denny has secured many friends by her attention to business and desire to accommodate." We are glad to see Miss Denny thus complimented.

THE W. Union Tel. Co.'s quarters in East Saginaw, Mich., have been removed to new quarters. They are spoken of as handsome and convenient. Mr. Ferguson has served the Company faithfully ten years, and still directs its affairs. Mr. F. G. Mann, once manager, is assistant operator. The East Saginaw press claim the office as the finest in the country.

A BOOK FOR EVERY RAILROAD MAN

THE HISTORY OF

THE FIRST LOCOMOTIVES IN AMERICA.

BY WILLIAM H. BROWN.

This is a deeply interesting as well as a very entertaining work. It is compiled from authentic records and original statements of old Engineers, who set up and run the first Locomotives in this country, and most of whom are still living. The work is elegantly illustrated. It contains a correct drawing of the first Locomotive brought from England in 1829, as well as of the first five Locomotives built in America, with their accompanying trains of cars.

EVERY RAILROAD MAN WANTS THIS BOOK.

Telegraphers can make money by canvassing or acting as agents.

Price..... $1 50.

Sent by mail, post paid, on receipt of price.

Address, F. L. POPE & CO.,
78 and 80 Broadway (Room 51),
P. O Box 6010. New York.

ON THE SPEED OF WORKING TELEGRAPH CABLES.

Theoretically the maximum speed is obtained on a telegraph cable when the ratio of the diameter of the conducter to the insulator is 1: 1·649. This fact originally pointed out by Sir William Thomson, has not hereto been taken advantage of to such an extent as might have been desirable. The reason of this is that it has been feared that the thickness of the insulator which would be required to protect the conductor would not be sufficient to resist mechanical injury. It is possible, however, that trade interest may to some extent have operated, because larger profits are derivable upon gutta percha than upon copper. For the covering being mechanically good, the nearer the conductor and insulation approach to the oretical ratio, the better the cable will be in commercial point of view; inasmuch as the same capital will procure a cable whose working capacity is greater; the working capacity representing directly the dividend which can be earned by it. The increasing scarcity of insulating gums will probably tend to induce manufacturers to find means by which, consistently with mechanical goodness, very much less insulating material may be expended. The nearest approach made as yet to the theoretical ratio of maximum speed was in the Malta-Alexandria (1861) Cable, in which the core, consisting of equal weights of copper and gutta-percha the thickness of the insulating material was was within five per cent, equal to the diameter of the conductor.

To the Editor of the Journal of the Telegraph:

Will you please answer, through the JOURNAL, if managers are to furnish "postage" for all business circulating between offices, such as "Error Sheets," copies of "Free Messages," &c.? MANAGER.

Answer.—On all legitimate business connected with the telegraph service the company pays all postages.

COWAN, TENN., Dec. 14, 1871.

To the Editor of the Journal of the Telegraph:

Please give notice of the offices opened on my lines:

Sewanee, Tenn. Tariff, 50 and 5 from Cowan.

Tracy City, Tenn. Tariff, 75 and 7 from Cowan.

This line is just completed, and is termed "Sewance Telegraph Line." It is built of No. 10 Gal. wire, and works like a charm, with 15 cups. Calland battery distributed at each end.

Yours,

J. M. STEWART.

MARRIED.

EYSTER—COPELAND.—At Washington City, D. C., Dec. 19, 1871, by Rev. Dr. Butler, Wm. R. Eyster, of Washington county, Kansas, to Miss Sarah E. Copeland, of Washington City, D. C.

WOODARD—WHITNEY.—On the 7th inst., at the residence of the bride's father, Waterford, Pa., Mr. Anson H. Woodard, Manager Waterford office, to Miss Emma A. Whitney, of the same place.

PILLOW—GRAY.—At the residence of the bride's mother, near Des Arc, Ark., December 12, by Rev. Dr. Gray, Mr. B. S. Pillow, manager W. U. Tel. office, De Vall's Bluff, to Miss Mary A. Gray.

MAXEY—MILLER.—At the residence of the bride's father, New Haven, Ky., Wednesday, December 13, 1871, by the Rev. V. E. Kirth, of Lebanon, Ky., Mr. J. W. Maxey, manager New Haven office, to Miss Addie Miller, of same place.

WHITTINGTON—FEWELL.—On Tuesday, December 12, 1871, Mr. C. H. Whittington, manager W. U. Tel. office, Manassas, formerly of Alexandria, Va., to Miss Maggie Fewell, daughter of W. S. Fewell, of Manassas.

DIED.

WITHINGTON.—At Springwater, N. Y., of consumption, on the 12th inst., Susie J., wife of Geo. E. Withington, manager W. U. Tel. office at Springwater, aged 22 years, 5 months, and 16 days.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 4. NEW YORK, JANUARY 15, 1872. WHOLE NO. 101.

GALVANIC BATTERY ELEMENTS.

From the Mechanics' Magazine.

Having made a number of tests, with various galvanic battery elements, with a view of determining their respective adaptabilities for telegraphic, signal, clock and similar work, their relative costs, constancy and strength, I send you a brief account of the results, thinking them to be of sufficient general interest.

The following cells were prepared :—

A. Leclanché's, zinc, ammonic chloride solution in water, and manganic oxide, mixed in the state of coarse powder with fine crushed best gas carbon, and packed with larger pieces of carbon in a porous cell around a carbon block. Reduced probably to dimanganic trioxide.

B. Similar to *A*, with the substitution of plumbic peroxide for manganese, and sulphuric acid, 1 to water 25, for the ammonia solution.

C. A modification of Marié Davy's element, zinc, sulphuric acid, 1 to water 25, and mercuric sulphate, securing equal electromotive force or potential, and much greater constancy.

D. Zinc, water, and plate of carbon, the latter descending to the bottom of the receptacle, and dipping into a layer of mercuric sulphate. Zinc and carbon closely approximated ; no porous division.

E. Highton's new element, zinc, ammonic sulphate solution in water, and carbon in porous cells packed with crushed carbon, and surmounted by a tower of cinders. Was made as closely as possible according to the inventor's description, the porous cell being selected for porosity and size, being 3 inches in diameter, and extending to a distance of about 6 inches above the surface of the solution, the upper part being pierced with numerous holes.

F. Zinc, sulphuric acid, 1 to water 25, and carbon packed exactly as in element *A*, *minus* the manganic oxide.

G. A new cell.

H. A new cell.

I. A new cell.

The elements *C*, *G*, *H*, *I*, if still satisfactory after further research and modifications, will be made public. All zincs exposed equal surfaces to solution, porous cells, with the exception of *E*, being precisely similar, and saturated for an inch from the bottom with paraffin ; chemicals, with the exception of acids, being the ordinary ones of commerce ; zinc, ordinary best Belgian rolled ; and the weight of substance at the negative pole, being in each case, except *E* and *F*, sufficient to neutralize the hydrogen displaced by one ounce of zinc. Current variations were determined by a very sensitive tangent galvanometer.

A word of explanation will be necessary respecting the electro-motive forces as entered in the table; these were measured, often poles were connected for two seconds by a resistance of ·197 Ohms. By this method I think a more correct estimate can be made of the practical value of the elements, for the potentials, though constantly falling on a short circuit, decreases to a very remarkable extent during the first two seconds only, the fall after that interval being small in comparison, the ratio between the force tending to produce a current ; and the current that can be maintained, even on long circuit, differs to a remarkable extent between the various descriptions of cells. For example, the element *A*, by connecting with a condenser of not too extensive a surface, and discharging through galvanometer, indicates about 1·49 Volts, whereas if tried after two seconds of current through ·197 Ohms, indicates as in the Table only 1·137 Volts, being then considerably less than some elements whose initial forces are much less than that of *A*. It is quite evident that the force as estimated by first method is seldom, if ever, available in practical telegraphy, especially in charging cables of great electro-static capacity ; whereas, by the method pursued here, results are obtained that can with confidence be accepted. The electromotive force was in each case invariably determined by three perfectly distinct methods, namely, that indicated above ; the method of Fechner, or Wiedemann, by the sum and difference comparison, and the other method due to Fechner, of direct comparison of currents through high resistance, using a zinc galvanometer of great delicacy, of 2,000 turns of fine wire and a resistance of 4,560 Ohms. Zincs being weighed, and poles insulated for 60 minutes, the potentials (E) were measured and inserted in Col. 2 of Table. After 13 hours open they were coupled in series, each one working through a resistance of ·197 Ohms. for 60 minutes, the variations in current strength during that time denoting an increase or decrease in the same respectively, unity in this and all other determinations being taken as that current producing a deflection of 45° on a certain galvanometer. After 36 hours from this time had elapsed with poles insulated *E* was as in Col. 4. Working in the same conditions as in Col. 3 for six hours, the variations determined are in Col. 5. after which the variations with open poles in 15 minutes, were entered in Col. 6. Col. 7 shows the potentials one hour after the last experiment. In Col. 8 is the current variation in twelve hours through 379 Ohms. Col. 9, 10, 11 shows the variations in three consecutive intervals of five minutes each through ·197 Ohms. only. Col. 12 contains the variations in the next five minutes through zeno. The potentials after two hours open poles were then found to be as in Col. 14. The absolute resistance of each cell was undetermined, but their relative resistances were ascertained both before and at the termination of the tests. In Cols. 15 and 16 are indicated by numbers the inverse order of the resistances, that is to say, from the most to the least conductable, before and after the experiments respectively.

ELEMENTS,	2. E. Initial.	3. Var. 60 min. after 13h. 19 ohms.	4 E. 36 hours after.	5. Var. 6 hours. 19 ohms.	6. Var. 15 min.	7. E. 1 hour af ter.	8. Var. 12 hours. 379 ohms.	9. Var. 5 min. 197 ohms.	10. Var. 5 min. 197 ohms.	11. Var. 5 min. 197 ohms.	12. Var. 5 min. O.	13. E. 2 hours after.	14. Loss. Zinc grains.	15. Order of $\frac{1}{R}$ initial.	16. Order of $\frac{1}{R}$ final.

Digitized by Google

Poles were then insulated for 18 days, and loss of zinc since commencement of tests ascertained to be in grains as in Col. 14. The zinc of *A* was in the best condition, smooth and clean, but with a few small crystals. *E* was slightly more attached, but covered with a quantity of large crystals forming a continuous coat. *C*, *G*, *H* and *I* were quite clean, but slightly pitted and rough on the surface. *B* was quite dirty, very rough, and traces of much local action. *D* was perfectly clean, but very much attached, and great local action.

The results I think afford sufficient data for valuable inference. I should select *G* where great constancy is particularly essential, and final cost a consideration, the negative pole of this element being absolutely and perfectly insoluble in the solution, and unaffected thereby for any length of time, and the cost of replacing it very small indeed. When continuous action with high electro-motive force is required element *C* is indicated. The same on short circuit, where conductibility is, and expense is not a consideration, will indicate *D*. When the battery is not to be called upon for an indefinite length of time, and then only occasionally, and on long circuit, element *A* should by all means be selected, especially if placed in inaccessible position, the cost of maintenance under such conditions being remarkably small, practically nothing. When, however, great economy of working is essential, and constancy not particularly necessary, the element *E* is certainly the best, if it is to be rather constantly used, and on long circuit.

South Kensington. W. H. Coffin.

CORNELL UNIVERSITY.—A STUDENT'S LABOR FOR KNOWLEDGE.

A correspondent of the New York *Times*, recently visiting the Cornell University, describes, among other interesting particulars, a conversation held with one of the students. The interview gives a good indication of the qualities of the young man, who is a sample of a great many, in the Cornell and other institutions of learning, who are obtaining an education under what the world would call adverse circumstances. But although the labor is hard, and the deprivations great, they form the furnace of trial, to refine the intellect, and produce a mental and moral state of sterling purity and value.

"I looked around for some student who could inform me as to the progress made in the specialty of Cornell—the self supporting part of the system. At last, by good chance, I came upon a room where a young fellow of twenty-three was studying Sanscrit. Having been in India for many years, I was interested in his studies, and we commenced an animated conversation upon philological roots. We criticised Max Müller, commented on Bunsen's theory of the Pelasgic people, and heartily agreed upon the absurdity of studying Greek and Latin, which were dried sponges, out of which everything good had been taken by our ancestors. Incidentally I learned that this most accomplished gentleman was supporting himself by laboring on the farm. He generally worked three hours a day, and six hours on Saturdays, and had already got through his appointed labor for that Saturday. I asked him if the manual labor of ploughing, etc., did not stupefy him, contract the brain cells, and make his apprehension duller. He replied that it did not, because he had been brought up as a farmer, and had nothing to learn when he came to the college. He was taking the agricultural course, but had become interested in philology, and one of the professors, who knew Sanscrit, had become interested in him, and had given him lessons in that perfect language, though Oriental studies are not in the curriculum.

I said: "I suppose yours is an individual case?"

Student—Yes, as regards the philology, but not for the farm. There are twenty-nine of us who work on it.

Correspondent—Does it pay your expenses?

Student—It pays mine; but then I worked steadily during the long three months' vacation, which ended in September. I can go easy now if I feel inclined.

Correspondent—I suppose the hardest part of the work is done by laborers employed for that purpose?

Student—Not at all. There are only two teamsters hired on the farm, and all the other work is done by us. At this moment we're laying down a series of drains, and this is very heavy work indeed.

Correspondent—Did you do that this morning?

Student—Yes, for six hours.

Correspondent—And did you not feel stupefied or tired out?

Student—Not at all. I dislike the work, and was very glad to get back to this, but I was not tired.

Correspondent—Are there any other methods of earning one's support here, besides the farm?

Student—Oh yes. If you can print, you can earn more in the press room than on the farm, and soon there will be lots of work in the machine shop. The men are going to make copies of Ollivier's geometric models.

Correspondent—What's that?

Student—Why, a Frenchman of the name of Ollivier made a set of models to illustrate all the problems of geometry. A set was purchased by the State of New York, and is, I think, at Albany. They are going to make copies of these. Twenty thousand dollars were given, I believe, for the first set that he made, but our fellows here can make them for eight hundred.

Corbespondent—I see. Well, but men who can't handle tools will not be able to do that sort of thing.

Student—Certainly not. Skilled labor is at the same premium here that it is elsewhere

Correspondent—What can the men do who have only their manual strength?

Student—Well, they can work on the farm or they can grade the square.

Correspondent—They can do that, but then do they?

Student—As a general thing they attempt it, and finding it rather rough, give it up in despair, and go home.

Correspondent—Well, but that was hardly what Mr. Cornell designed, was it?

Student—No, he expected that the college would give work to every one, that cared to take it, of a kind that he could do. I suppose that this will be done in the future by outsiders, but it can never be accomplished by the college.

Correspondent—Something in the factory way, you mean. I suppose something that will utilize the grand water power that is runing to waste so picturesquely in the gorges.

Studenl—(laughing)—I guess so. I have heard that Mr. Cornell has some such scheme in his head.

Correspondent—But even then, perhaps, the men could not earn enough to keep them. Let us calculate a little. I have been through some factories in Auburn lately, and I learned the rate of wages current there. Such work as unskilled students could do would be paid at the rate of seven, say eight, dollars a week for a day of twelve hours. Now, how many hours can you average of work throught the year?

Student—About half a day if I work steadily through the vacations.

Correspondent—Very good; then that will only be four dollars a week throughout the year for everything.

Student—That would be quite sufficient. My expenses are only three dollars a week, and I earn enough over to keep me in coarse clothes.

Correspondent—I beg your pardon for the seeming impertinence of the question I am about to ask, and I beg you to believe that the spirit that dictates it is not one of mere curiosity. Are you living in this fashion from necessity, or do you perhaps wish to show that it can be done by those who have no resources?

Student—I do it from necessity; I am very poor.

Correspondent—Sir, from my heart I honor you, and if the sympathy of a stranger can lighten a road so stony, pray understand that you have it in the fullest sense of the word.

We shook hands heartily, and I left him to his Sanscrit, feeling as I walked away that Cornell meant something more than showed on the surface. We Americans have been rather apt to worship the dollar, but when poverty is so honorable and so honored as it is here, our golden idol is like to tumble a peg or so in the estimation of society."

STATE RATES.

Ontario, Dec. 30, 1871.

To the Editor Journal of the Telegraph:

Dear Sir:—I am glad to find that you hinted at a probable simplification of your tariff, in a recent number of your Journal.

The idea occurred to me long ago, but I hesitated about suggesting it, for various reasons.

The adoption of a uniform rate over the Montreal Telegraph Co.'s lines, has simplified our tariff and booking arrangements wonderfully, and an approach to a uniform rate in the United States, would reduce and simplify office labor. I do not advocate a uniform rate all over the United States, as the territory is too great—but a certain rate from any place in one State to any place in another, thereby reducing your *tariff sheet* to the dimensions of a small card, for distribution among your customers. A tariff sheet of about forty squares answering for the United States.

Yours, G. B.

An Interesting Case.—*Liability of Telegraph Companies.*—Some months since, Mr. George T. Dickerson entered suit against the Western Union Telegraph Company, claiming $5,000, because of the negligence of the Company in the delivery of a message, by which he was not informed of his sister's death at Syracuse, N. Y., until some days after the obsequies—the telegram having been directed to Gen. T. Dickerson. The defendant demurred, on the ground that the declaration showed no right of action in plaintiff against defendant; that it does not disclose he had such an interest in the subject matter of the dispatch as to entitle to sue for negligence, and it does not appear whether the defendant is sued for cause arising *ex contratu* or *ex delectu*. The demurrer was argued by Mr. Trigg for plaintiff, and Mr. N. Wilson for defendant, and a few days ago Judge MacArthur announced his opinion, sustaining the demurrer. He discusses the liability of telegraph companies; holds that in this case the plaintiff sustained no pecuniary loss; but, on the other hand, the circumstance of not receiving the message in time, would bring to him sympathizing friends, &c., and, as he was not the contracting party, the telegram having been prepared elsewhere, he has no right of action.—From Washington *Star*, Dec. 30, 1871.

THE INSTITUTION OF CIVIL ENGINEERS.

The opening meeting of the new session of this Institution was held in Great George street on Tuesday evening when the paper read and discussed was on "Pneumatic Dispatch Tubes—the Circuit System," by Mr. Carl Siemens, M. Inst. C. E. The chair was occupied by Mr. Vignoles, F.R.S., the President. In April, 1863, the Prussian Government applied to Messrs. Siemens and Halske, of Berlin, to suggest a system of pneumatic tubes for that city. That firm proposed laying tubes, arranged in circuit, to be traversed by a continuous air current always kept flowing in the same direction. The peculiarities of this system—namely, the continuous current of air and the power of putting carriers into the tubes at any point—gave it great superiority over previous systems in the amount of work it was capable of doing. The Central Telegraph Station and the exchange of Berlin were connected together on this system in 1865, by means of two parallel lines of drawn wrought-iron tubing, of two and a half inches internal diameter, one tube being used exclusively for the passage of carriers in one direction, and the other for carriers going in the opposite direction. The continuous current of air for these tubes was produced by means of a steam engine working a double acting air-pump in the basement of the telegraph station. A minute account was given of the experimental circuit laid by Messrs. Siemens between the Central Station in Telegraph Street and the General Post Office in St. Martin's-le-Grand, which was opened for traffic in February, 1870, and had subsequently been extended to Fleet Street and to the West Strand office. The different Stations were connected by two lines of wrought iron tubing, having an internal diameter of three inches. Both lines were laid in the same trench, at a depth of about 12 inches below the pavement, and parrallel to one another. The tubes forming the circuit were of an average length of 18 feet 8 inches, a common lead-and-yarn joint making the connection between each tube. A current of air was kept constantly circulating through the tube by means of a steam-engine and double-acting-air-pump placed in the basement of the Central Telegraph Station. Each station on the circuit had two sending and receiving instruments one on the up and one on the down line of tubes. The carriers for the reception of telegrams, letters, &c., consisted of small cylinders made of gutta-percha, papiermache, or tin, covered with felt, drugget or leather. It was found in practice that the carriers need not fit the tubes at all accurately. Mr. Culley, M. Inst. C.E., chief engineer of the Post Office Telegraphs, had adopted the block system, such as was used on railways for working the tubes. Various tables of formulæ and results were referred to and explained. The total length of line now working in London, from Telegraph Street, to the West Strand office and back, was 6,890 yards. It was found by experiment that the speed of the carrier was much greater as it approached the vacuum end of the tube than it was at the other end. The necessity of having a steam-engine with air pumps and reservoirs was a great hindrance to the general introduction of pneumatic tubes, but this inconvenience had been succesfully removed by the construction of an exhausting apparatus working by the direct action of steam upon a current of air. With one of these exhausters a vacuum equal to a column of 23 inches of mercury was obtained with a less expenditure of steam than would be required to work a steam engine and pump to effect the same object. The principal recommendation of the steam exhauster, besides its extreme simplicity and the small space it occupied, was its cheapness of construction, as the cost only amounted to about one-twentieth part of an engine and pumps. Up to the present time, so far as the public was concerned, the pneumatic tubes in London, Berlin, and Paris had only been used for the conveyance of telegraphic messages, but the British Post Office authorities had already considered the question whether it would not be advantageous to have the letter post service in London executed by means of pneumatic tubes. With such a system of distribution an accumulation of letters at principal offices would be entirely avoided.

ELECTRICAL ANEMOMETER.

A new form of anemometer, the invention of Mr. J. E. H. Gordon, has just been constructed by Mr. Apps, and seems likely to prove of material service to all who desire to notice and record the direction and velocity of the wind. The instrument was briefly mentioned in the *Times*, last April, in the report of a *soiree* given by the President of the Royal Society, but the one there exhibited was in some respects incomplete. As now made, the anemometer consists of an ordinary pair of Beckley fans and a set of revolving cups, fixed in any convenient situation, and connected by insulated wires with a galvanic battery and with a recording apparatus. There is no limit to the length of the connecting wires, so that, for example, recording instruments at Lloyd's might be connected with fans or cups at any part of the coast. The recording instrument itself consists of a clock, a wind dial, a reel of paper, and an endless band carrying a carbon paste for printing. The dial indicates the direction of the wind, and the printing band prints this direction every half hour. The same band records every quarter of an hour of time and every completed mile that the wind has traversed. The slip of paper issued by the machine is about an inch broad, and it receives the time on its left-hand margin, the direction of the wind on its right-hand margin, and a dot for each mile on a central line, so arranged as to be comparable with the time record. The number of dots marked on the paper between 10 and 11, for example, indicate the velocity of the wind during that period of time, and the dots become crowded as the velocity increases, and stand farther apart as it decreases. The battery is composed of zinc and carbon elements, with dilute sulphuric acid, and will work for six months without attention. The reel of recording paper holds a supply for three months, and the clock can be made to run this length of time without winding; so that the whole apparatus would be as nearly as possible self-acting. Ordinarily, however, it would be desirable for the attendant in charge of it to date the recording slip every twenty-four hours, and an eight-day clock would be sufficient for the requirements of most observers. The great advantage of the instrument is in the character of its record, and in the fact that the electrical communication does away with the use of cranks and shafting, which are not only costly and heavy and far less delicate, but which also render it necessary that the recording instrument should be in the immediate neighborhood of the fans.—*Times.*

A GENERAL meeting of the China Submarine Telegraph Company has been held at the Cannon street Hotel, London. The report stated that the line had now been opened five months, and was earning a dividend at the rate of 6 per cent. per annum.

THE British Australian Telegraph Company have received a telegram from Captain Halpin announcing the successful laying of cable from Port Darwin to Banjoewangie, in the island of Java.

A MODEL OPERATING TABLE.

To the Editor of the Journal of the Telegraph:

It is two years since the first circular stand-up operating table was constructed, necessity was the maternity. The room, in which had to be worked 7 wires with an instrument on each, was only 13 feet square. The table is a circular disc, 6¼ feet diameter and stands 39 inches from the floor. The results attained through its peculiarities are various. A large portion of the through business has been forwarded (repeated) to the next office while still coming from the first. A still larger portion has been forwarded within a minute or two of its receipt. Crowded wires and sometimes short force, with a sprinkling of offices, hard to raise, have been the main drawbacks to still better results. The table has now eight wires, and upon these we reach 59 offices direct, and some of these offices we can reach on 2, 3, 4, 5, 6 and one on 7 wires. Without turning the head one can watch the chances for an idle circuit on every wire running into the office wanted, when the receiving operator gets as far as the destination he calls it out loud enough to be heard by all, and when a message is taken at the counter, the private signal of the office to which it is to go is spoken the moment it is ascertained, so you see that a message must have a poor chance for a rest if there is an operator who is not engaged.

Above the table is a light wheel 4 feet in diameter. This revolves easily, and is divided into eight sections with hooks and names of offices, each section over its appropriate instrument, when not being moved to take off or hang up a message.

There are four other wires in the office, three of which we work, these have 37 offices, most of them not on any of the round table wires. The messages destined for points on these wires, are also hung on the wheel, so that every operator in the office knows at all times, without even turning to see, for which and for every office we have business, for all constantly face the wheel and no one can well escape seeing the very play of expression upon the countenance of the other operators.

As we are all good looking, this is not disagreeable. Standing was, at first, very tiresome, so we got a couple of stools that we might rest. *Now* the stools are, for the most part, entirely abandoned. I find that the less the height of the heel to my shoe the less the fatigue, so I have let my heels run down almost even with the sole. I am never so tired, at the close of my work, as I used to be after sitting all day. I think we all enjoy better health than if we were more sedendary. I hope to see the President of the Company come to look at it, and now, though I have before described this in the JOURNAL, let me make you a drawing of it. Very respectfully, * * *

NOTE. We may give a wood-cut of this table in some subsequent number.—*Ed.*

It is manifestly impossible for us, or for any news paper in Japan, to obtain exclusive telegrams from Europe at the existing rates. Added to this, there is the fact that the *Straits Times Extra*, which, before the completion of the cable to Hong Kong, published very full telegrams, is now only able to furnish the most meagre information, and that of a by no means recent date. The merchants here are naturally not inclined to increase their expenses by subscribing for any but commercial telegrams, and these latter they get privately from their correspondents at home, and, under these circumstances, we have every right to call upon the telegraph companies to permit of such arrangements being made as will enable us and other journals in China and Japan to publish full telegrams on the arrival of every mail.—*Yokohama Mail, Oct.* 31.

FAMILIAR TELEGRAPH TALKS.

We don't get on very fast, so far, with these talks, and it is just as well, for there is plenty time before us, and, at school, we believe in short hours, pleasant lessons and lots of holidays. In our last we were learning the alphabet, Professors Smith and Pope doing the talking for us. We had an objection from Bangor, Maine, about the correctness of the semi-colon, but we gave it as employed here and presumeably correct.

It is a very curious thing, in connection with the manipulation of the key, that even here, every one has such an individuality of thought and motion that, as in the use of the pen, where a thousand men will each make the same letter so differently as that each handwriting shall be recognized, so with the key, the touch shall tell who is manipulating it. We remember well returning one afternoon from New Orleans to Louisville, Ky., walking into the operating room while one of the eastern operators was absent, we sat down, called G., and sent two messages then on file. We gave no signal to denote our presence there. We had been absent many months. We had not touched a key for a year or more. Yet as soon as we had finished the response came back, "O. K. 73, to you J. D. R. how are you?" A little surprised we asked how it could possibly be known that we were at the key? "Oh," was the speedy response, "we know your writing anywhere." Now this seemed very curious to us then. We were conscious of no peculiar manner of forming letters except that we attempted to make the letters as near correct as the type. Yet our case was not peculiar and we are told that each operator seems in some subtle way, distinguishable to the ear, to prove whether Tom Jones, or John Smith, or Jim Compton is working at the key.

It is another curious thing against which we feel like protesting, that to learn to form letters by the register, which we have insisted upon as necessary to their correct formation, is to unfit the learner for sound writing and reading. This, we confess, is beyond our comprehension and stultifies our judgement. Yet it is not more curious than that on some lines, if a message were sent with mathematical correctness, the dots and lines sharply defined, it would not be understood. We have seen recorded messages manipulated by first-class operators which we could no more decypher than Sancrit, but which were quite intelligible to the receiver. We don't like this to be the case. It is making a kind of Scotland of the telegraph, where every few miles you travel you find the language in some peculiar way changing, until from the softened english of the metropolis you reach the jaw-breaking patois of the highlanders. We believe in sticking to the original standards with scrupulous care and fidelity.

Well, we are a little hurried this week and will be brief. We have learned the alphabet carefully, and learned to communicate in the only way in which it can be thoroughly mastered, by keeping up a communication with some one on a wire circuit, not necessarily in transmitting business, but in keeping up animated conversation so as to remove all fear although preserving the care in the use of the key. An office is applied for and obtained, and now it is the business of the new operator to look round him and see that he has fair play, and that he has a fair chance to use the knowledge he has thus far obtained.

The post assigned him is a way office. The line passes in front of his window. To connect him with the offices of the line the wire is cut and a glass nob is inserted to break the connection so as to establish it through the office. It is deemed quite good enough by the agent sent to do the work and no doubt many deem it so, it is done so commonly. Now, young operator, go out and see that at this point you are not placed at a disadvantage. From the one side of that glass nob to the other there is a separation of the main wires of only two inches. When the current is made to traverse your office, before it reaches the terminals of the main wire at the knob, it will have had to travel the equivalent of at least half a mile even with a magnet of low resistance. The one route is 15,000 times longer than the other. Electricity likes a short cut as well as a man. It will take it if it can. It is your interest that not a particle of current crosses these two inches. Every flicker across that narrow bridge is against you, for it cheats you out of your working material. What will you do about it? Well, if you cannot prevent the connection been made in this way, persuade the agent to have two knobs inserted as far apart as possible, and instead of wire being used to hold the two knobs together, use, if you cannot do better, a tarred rope giving it a good coat before you leave it. We would not be content with even that. We would in some way plant a roof over both knobs so that they might be perfectly protected from rain. They cannot be kept from sweating when the air is warm and moist, for the cold glass will condense the air upon their surface, and that is the sole objection to glass as an insulator, but the coat of water given by the falling rain can be prevented. A little ingenuity will accomplish this. The loss by moisture at every point is the lesson of this talk. Let the wires be brought, if possible, to brackets on either side of the window where the brackets having been well soaked in parrafine and the insulators kept clean and covered this first evil is prevented. It is at such points where we deem the form and composition of the Brook's insulator or others bearing a high test and of a form to shed the water easily and freely are invaluable. One on each side of the window afford guarantees against hurtful escape.

One word more on this subject. Let the main wires be brought, if possible, inside of the office before the copper office wires are attached. If not, let great care be taken to see that the connection outside be carefully and thoroughly soldered.

We have personally been put to so much annoyance, from carelessness in making this very connection, that we advise every manager of such an office to see that his is thoroughly done.

A BEAUTIFUL TESTIMONIAL.

One of the most thoroughly surprised persons that last Christmas or any other Christmas morning ever dawned upon, was R. S. Fowler, Esq., Superintendent of the Iowa division of the Illinois Central Railroad Telegraph Lines. He was at his post on Monday morning, the same as other mornings, together with all the employes of the office, except Mr. E. Sholes, the report operator. About nine o'clock Mr Sholes made his appearance, and his first words to Mr. Fowler, were:

"Mr. Fowler, I wish you a merry Christmas. In behalf of many friends, I present you this watch and chain."

With this laconic address, he handed Mr. Fowler the watch and chain, and a paper headed as follows:

"TESTIMONIAL TO R. S. FOWLER.

"Please accept the accompanying watch and chain as a slight token of respect, appreciation and esteem from your many friends, who hope it will prove acceptable as well as useful. All unite in wishing you many happy returns of the day."

Following the above were the names of the donors, some ninety in number, comprising nearly all the operators belonging on the line.

Mr. Fowler was not only thoroughly surprised, but completely astounded; in short, there is no word in the language strong enough to express the utter unexpectedness of the whole affair. After a little, however, he managed to make his emotions of gratitude and pleasure understood to those in his immediate presence, while the following brief letter was transmitted along the line to each operator:

DUBUQUE, Dec. 25, 1871.

To my Friends:

The reception of so elegant a testimonial at your hands is indeed a pleasant surprise. I can but return you my most heartfelt thanks, and my sincere hope that the pleasant business and social intercourse between us, which has been uninterrupted for more than five years past, may continue through the return of many a merry Christmas!

Very truly yours, R. S. FOWLER.

The watch is one of the finest, if not absolutely the finest, ever brought to Dubuque. It is a masterpiece of the "United States Company's" workmanship, made at their celebrated factory at Marion, N. J., expressly for this occasion. It has ruby pallets, jewels set in gold, nickle plate, enameled and frosted, and an eighteen carat case, with vermicelli engraving. On the front is the monogram "R. S. F.," most beautifully designed and engraved. On opening it, upon the inner cover of the works is the inscription—

"TO
R. S. FOWLER,
From his Telegraphic Friends:
Dec. 25, 1871."

The chain is eighteen carats fine, heavy, and of beautiful design and perfect finish. The works alone of the watch cost more than $100, and the expense of the whole was about $300. It was procured through the firm of E. A. Giles & Co., to whom is due much credit for the handsome way in which it was gotten up.

This is a case in which the gift is in every way worthy of the receiver, and the receiver of the gift—as not only his subordinates, but the public, who have daily dealings with the telegraph office, and have uniformally found Mr. Fowler always gentlemanly, prompt and painstaking, will unanimously agree. The recipient will constantly bear about with him an unsolicited testimonial of respect and esteem, of which he may well be proud so long as life shall last.

The Riband Telegraph Pole Company are erecting extensive works at New Islington, Manchester, and putting down plant capable of turning out 500 poles per day.

RESIGNATION OF MR. CHAS A. TINKER.

WASHINGTON, D. C., January 11, 1872.

To the Editor Journal of the Telegraph:

It having been rumored that manager Tinker had resigned his charge of the Washington, D. C., office, which rumor was subsequently confirmed by the appearance of the following circular:

WASHINGTON, D. C., January 9, 1872.

To the Operators, Clerks and all other Employes of the Western Union Telegraph Company, Washington, D. C.

Unexpected inducements opened to me elsewhere, have prompted my resignation of the Managership of this office, but before closing my official career, I desire to express thanks to my many associates for their generous support and faithful adherance to duty, to which is due the little success I have met with in the conduct of the various and oftentimes trying duties of the position. To each and all I am grateful, and very many regrets swell my heart at the thought of severing these pleasant relations of nearly five years existence; but the pangs of seperation are half buried in pleasant memories, which will be ever present with me in whatever station my future may be cast.

I have also to announce the appointment of my successors, Leonard Whitney, Manager, and Morell Moreau, Assistant-Manager, both of whom are well and favorably known to all, and I believe you will, with me, accept this selection of two associates to represent the Company, and serve with you in the protection of its interests and performance of the work required of its servants in this office, not only a special mark of esteem for virtues, and recognition of merit, encouraging to all, but an assurance that the affairs of the office are in a satisfactory condition, and a desire that they shall be so continued, under the guidance of experienced heads already familiar with them.

I bespeak for my worthy successor and his able assistant, the same cordial co-operation and support in their management which you have extended to me.

I shall leave you in a few days, conscious of having endeavored to bear faithfully my responsibilities to the Co., dealing justly with all, and cherishing a pride in my companionship with its employes of the Washington office.

Very truly yours,

CHAS. A. TINKER.

The employes conceived a plan for making some substantial manifestation of their friendship and regret at his departure, and did most successfully and happily execute it on the evening of the tenth instant, by a visit to his residence, *en masse*, bearing in procession a valuable silver service, consisting of a tankard, goblets, bowl and salver and a tea service of six pieces, exquisitely wrought, the tankard bearing the inscription, "Presented to Chas. A. Tinker by the employes of the Washington, D. C., office of the Western Union Telegraph Co., January 10, 1872," each additional piece bearing the monogram C. A. T., neatly engraved. The presentation speech was written on the initial leaves of a beautifnl autograph book, each following leaf bearing the autograph of one of the participants in the gift. The speech was gracefully made by operator James B. Austin, of the main office, as follows:

THE PRESENTATION SPEECH.

MY DEAR SIR:—As you are on the eve of severing your connection with the Western Union Telegraph Co., as its manager in this city, we cannot withold the expression of our regret in parting with you, perhaps never again to be associated in business relations. There may have been occasions when our dispositions, like the telegraphic wires in inclement seasons, have been unfavorably affected, but like the return of good weather and the manipulation of a skilful hand, there was the resumption of all the amenities which should characterize gentlemen engaged in the same pursuits. It is always at the moment of parting that we feel more strongly than we do at other times, that our association has been more pleasant than when we had no thought of seperation. We doubt not, in your distant home, you will often recur to your management in Washington, and though you have had sorrow and affliction, you will doubtless recall much of pleasantness which has attended your residence in this city. We join in the expression of the hope that your new vocation may not only prove agreeable, but profitable, and that you may enjoy a full measure of health, without which, there can be no enjoyment of wordly prosperity.

We ask your acceptance of the accompanying articles, which may serve additionally to remind you that you are held in kind remembrance by those who have been associated with you.

While all listened in perfect silence, but inwardly enjoying the predicament, into which, this time, they had entangled the wits of their manager. Mr. Tinker accepted the articles in a few words, indicative of his extreme happiness, best expressed in the surprise and pleasure depicted in his countenance.

Mrs. T. had been quietly advised of their plans, and exhibited her preparation by an invitation to the dining-room where a table was found abundantly provided for the occasion.

The evening was spent delightfully. Each hour passed *merry as a marriage bell* until midnight brought the "good night." It was an occasion long to be remembered by the forty, or more participants.

Mr. Tinker leaves us to enter upon the duties of General Train Dispatcher for the Vermont Central R. R., the position made vacant by the sudden death of the late Mr. Randall, referred to in a previous number of the *Journal*. His successors have entered upon their duties, and though we regret the loss of our late manager, we greet the new with a hearty good will.

VIVO.

NOTIFYING NON-DELIVERY OF MESSAGES.

MADISON, N. Y., Jan. 8, 1872.

Editor Journal of the Telegraph:

When I send a message to an office and get O. K. from it, and that message is not delivered, and no office message is received stating that it cannot be delivered, have I not done my whole duty? Is it not the duty of offices receiving messages, and who know they cannot be delivered, to notify the office from whence they was sent? The reason I ask is, that nearly every day some one comes and complains that their message were not delivered. I am new at the business and wish to understand my duty. M.

Answer. Rule 53, page 27, is as follows:

"In case of non-delivery, the reason in writing must be given by the messenger to the delivery clerk, who will notify the office from which the message is received, and will also make a record of the same on the envelope of the undelivered message."

Rule 56, page 27, reads as follows:

"Whenever messages cannot be delivered, in addition to notifying the office from which they were sent, notice should be given through the post-office written upon blank No. 26."

We feel conscious that neglect of this and similar rules, operate greatly to the disadvantage of the telegraph system, and whenever neglect is clearly proven, there should be such a reprimand given as will at least convince the offender of the extent to which the company feels the injurious character of the offence.

AUGUSTA, Maine, Jany. 2, 1872.

To the Editor Journal of the Telegraph:

DEAR SIR:—If Mr. Kelchner would correct a slight error in his communication, he would present a much stronger case. To read the numerous articles on this subject, one would suppose that the very existence of the W. U. Telegraph Co. depended upon the tariff and form of message being tinkered to please the public. Let us first do WELL what we have to do. It is not so much the tariff or the form of the message that the public have to contend with, there is trouble nearer home, which might be remedied in a great measure. First, there is errors; secondly, delays; thirdly, but not lastly by any means, is the necessity of having to send two or three office messages requesting answers to messages sent. Now here is something that operators and managers have right in their own hands to please the public with, and to increase their companies business, these evils can be in a great measure remedied, but it is in the hands of the operators and managers entirely; there is a way in which the Company can handle this matter, but it will take time to do it. Amongst the existing evils, and which is indeed the great cause of the three spoken of above, is fast writing and improperly spacing, attempting to write fast before learning to write slow, not being in fit condition to send or receive a message; lack of discipline on the lines; indifference and carelessness of operators in general.

ONE WHO SEES.

WE regret that a carefully prepared article describing the new St. Louis Headquarters of the Western Union Telegraph Company, reached us after our last was made up, and which would have taken the place of the one given from the St. Louis Democrat. We give the following which did not appear in that article.

THE ST. LOUIS STAFF.

District Superintendents Office.

R. C. Clowry, Superintendant 2d district.
J. McMichael, Chief Clerk and Supply Agent.
Jas. P. Cassidy, Assistant Clerk.

ST. LOUIS OFFICE.

E. H. Brown, Manager.
W. W. Osborn, Bookkeeper,
Thos. F. Tierney, Assistant Bookkeeper,
H. E. Losey, in charge of Commercial News Department,
Jno. A. Hobbs, Receiver,
A. E. Haquette, Assistant Receiver,
Jno. L. Rand, Assistant Receiver,
Jos. T. Holohan, Delivery Clerk.

Jno. C. Hanchett, Chief Operator,
Chas. W. Hammond, Assistant Operator.

OPERATORS.

Albert E. Van Tyne,	E. J. Stevenson,
Kit Dougherty,	M. G. Chettle,
E. L. Parmelee,	Chas. F. Benett,
Jas. W. Cooke,	Jno. H. Crane,
W. W. Cummings,	Jas. L. Cassidy,
J. G. Edwards,	M. D. Crain,
M. C. Hart,	S. B. Fairchild,
Joseph Purcell,	Jas. P. McClure,
Wm. A. Leary,	E. O. Martin,
R. H. Boble,	Wm. A. Hobbs,
Chas. Maginnis,	Jno. J. Reilly.

NEW RAILROADS.

Quincy to East Louisiana, Ill.

Kalamazoo to Smyrna, Mich.

Chicago to Dubuque, Iowa.

The Missouri, Kansas and Texas road will open Texas to the west and north early in June next, and is regarded as a very important road.

St. Louis to St. Paul, 502 miles by the Burlington, Cedar Rapids and Minn. R. R., has been opened to the public.

Keokuk, Iowa to Nebraska city.

PRINTING TELEGRAPH.—Richard Herring, of Canonbury, Eng.—This invention relates to that class of telegraphic printing apparatus in which the signals are effected by printing or marking dots and dashes or short strokes on a band or strip of paper as it travels through the apparatus. The object of the improvements is to increase the rapidity of transmission of the printed signals, and to simplify and facilitate the manipulation, and to render the signals easier to read and less liable to error. To this end, instead of making the dots and signals run in a line, the dashes or strokes are arranged in a verticle position. By this means the signal can be read with great facility. It takes up less space, and, it is claimed, can be transmitted with greater rapidity than the old style of signal. To effect this object a style or instrument of peculiar construction is employed. As it is composed of separate parts or styles, it may be termed a compound style. One of these parts is made in the form of a blunt, round point, so as to make or print a dot. The other part of the style is made with a long narrow edge, so as to form or print a dash or stroke; or, by means of any combination or construction of the style or styles, any other signs which may be deemed preferable to adopt may be used. In any case, the two parts are operated by seperate currents of electricity or by distinct magnets.

A LARGE quantity of matter is necessarily laid over until next issue.

NEW YORK, JANUARY 15, 1872.

INCIVILITY.

The text is not agreeable and we would rather select another. But to preach acceptably there must be the pressure of some vital thought which demands utterance. Our desk covered with com plaints of the character indicated by our title, one of them ten folios long, obliges us to say a word respecting them. We cannot publish them all. One of the mildest, from Augusta, Me., is given. We must have condensation if parties would have a place in the JOURNAL. Yet we take up the subject of them all when we say, that there is evidently on the part of some, it may be of many, a style of performing their duties, which indicates a low and reprehensible conception of the nature of their business, and of the treatment due to associates in labor.

Here, for example, is an operator, anxious to do his duty. He sends a message to an office, but does not hear, or thinks he has not received the acknowledgement. He is not satisfied unless sure of its reception, and asks, politely, "did you get my message?" or some other such respectful inquiry. A sensible man would at once respond, "O. K," and thus at once relieve anxiety. But how harsh it comes, how offensive, to have flashed back, "mind your business, and don't make me answer twice." *That* man ought to be charged, at least, the price of a message. Or an operator sends a message containing some anxious inquiry. The sender lingers round the office counting the minutes and the laggard hours as they pass. The operator, after waiting a reasonable time, ventures to call the distant office, and inquire if answer has been received. His anxiety to satisfy the customer may be excessive, but it is an anxiety which every true man must, more or less, feel. The mere answer "no," would perhaps relieve it. But how does it make the teeth meet, when the unseen bear growls back, "shut up, you will get your answer when it comes." We would like to believe there were no such men; we would be glad if we could "shut" them all "up." We would like to give such a man a night on an iceberg with a polar bear as an initial dose. It might give him proper *polarity* if he escaped unchoked. Incivility on a telegraph line, is simply detestable and cowardly.

And the trouble is, that these vulgarities are secret sins. An operator is not willing to report any such conduct, however mean, even when he knows that the business is made to suffer. So he is silent, and the bear lives. We often contemplated a plan to check all this, when lines were under our management. We thought once of a plan, by which all communications would register themselves, so that the whole manner of official intercourse would be revealed, and a remedy be thus swiftly applied. We took, however, another course—Listen!

Near where we write is a restaurant, the principal is rich and domineering, he talks to his waiters as if they were dogs. What then? Only this, they are dogs to each other, snapping and growling curs, between whom no civil word passes from morn to night. The men are the master in hash, and we scarcely blame them; it is so everywhere. Like produces like; it is the correlation of forces.

Well, we must speak our experience sometimes, even if we be called egotistic therefor. We tried the correlation the other way. We visited the offices frequently, sat down at the desks of our men and helped them. We dropped into their households now and then; we hailed them from the platform, and kissed our hand to them. Ladies will please notice we said "hand." We shook hands with the messenger boy, as his pleased face lit up with a smile, which followed us to the cars. Not unfrequently in Cincinnati, in Louisville, in New Orleans, we accompanied each other to church. Ha! ha! ha! We see some executive officer smiling at all this. Very well. It worked well enough. We had no shirks and no bears; they went elsewhere. By its power, we kept up a supervision from New York to New Orleans, in which the elements of courtesy and vigor equally shone, not in us, but throughout. We believe in the system. There are many men doing today, what twenty-five years ago we began. There are no hogs in their whole district. There is combined the utmost vigor, with the most perfect respect. Advocates of government telegraphs don't live in their region. We commend the medicine. We have seen "how the new thing works."

As all railroads as soon as completed are at once regarded as post roads, the Post Office Department is, of necessity, kept fully informed of the progress and completion of all railroad enterprises. This information embraces not only new independent roads, but also all branches and extensions of old routes. Nothing more clearly exhibits the enterprise of the country and the progress of the population. Few people are aware of its extent. In no single period has it been so marked and extensive as during the months which closed the now departed year. December far exceeds the average of any former month. The following figures are sufficiently remarkable and need only to be stated to give some idea of the energy which pervades the country. In fourteen States, twenty-nine railroads have been completed, forming new post routes, in all 968 miles of railroad completed during the month, and there seems no signs of the least abatement. Before us, as we write, lays the *Railroad Gazette*. It is the most royal and ample weekly which reaches our desk. Let us turn over its pages. There are page after page of the record of railroad improvements and the progress of invention. All is fresh, animated, sparkling, stimulating. Then we come to the history of railway progress. It is headed "Roads, Old and New." Column after column it gives the details of roads just completed and open for travel; roads in progress; roads projected; roads needed. In short brief articles, two or more pages are commonly filled. Nothing could better indicate the push and swell of population, the growth of public demand for enlarged commercial transit.

And some one asks for the hundredth time, "what has a telegraphic Journal to do with this?" We need scarcely answer. No road can now be built without a telegraph along side of it, if it would escape scorn and disaster. The history of railroads must be ever, more or less, associated therewith. A railroad means not only a postal route, but a line of telegraph as well. This always, and by the very necessities of the case.

Hence may be seen the necessity of constant provision, by a company like the Western Union, for the means of enlargement. One thousand miles of railroad opened in December, means one thousand miles of telegraph added to the American telegraphic service. And so it must be ever if a great company would be true to itself and the public. It cannot afford to stop its work. To cease the processes of enlargement, while civilization surges its big waves on every side, is to die.

"*Only this, and nothing more.*"

A number of articles have been set afloat intimating a design on the part of the British government of gaining possession of the Atlantic cables. In others the government of the United States is included in their proposed control. If there be, indeed, any proper sphere in which governments can work in telegraphic enterprises, as we have taken occasion to say more than once in these pages, it is in the matter of planting and maintaining Ocean cables for international correspondence. We were induced to say so from their great cost, their doubtful continuity, and the exposure of capital involved therein, as well as to insane competition started by cable contractors—imperilling all investments therein. Governments could afford, in the general interest of civilization, to make a sub-oceanic transmission practically free, maintaining the conductors from coast to coast, leaving internal arrangements to private enterprise on certain defined conditions. We see, however, no immediate indications of such a result, unless this be what Mr. Field meant in his Rome speech, when he spoke of the necessity of appealing to governments for aid in developing and maintaining the great telegraphic connections of the world.

VOLUMES 3 and 4, Journal of the Telegraph neatly bound, can be supplied. Price two dollars each.

THE NEW NEW YORK OPERATING ROOM.

On Thursday, January 11, at 4 P. M. in presence of the Executive Board and Officers of the Western Union Telegraph Co., and representatives of the New York Press, the new operating room described in a former issue was taken possession of by the operating force. The switching from the old room to the new was a complete success, and the business experienced no further interruption than the time needed to reach the new quarters. Steam was at once applied to the tubes copying presses and printing instruments and all went off charmingly.

After the guests had had time to comprehend that the transfer had been effected, business was stopped while President Orton addressed those present as follows:

MR. ORTON'S ADDRESS.

GENTLEMEN—I take this occasion, now that all are comfortably seated in this new and elegant apartment, to return thanks, in behalf of the company, to the General Superintendent, the Superintendent, the Managers, and all who have in any way aided the completion of these beautiful and unique arrangements. They are the result of twenty years experience in the developement of the telegraph system of this Continent, and typify the skill so far attained. What another twenty years will develope time can alone reveal, and for it we must wait.

To those who perform the toil connected with the service of this apartment I desire to say, that I trust all will see in these arrangements and in the beauty and comfort of this room, the design of the officers of this company to do all that can be done for the welfare of those who serve them. If gentlemen, you will in the future give us the vigor and the cheerfulness and the skill which has marked your past service, I feel assured that we shall together build up a telegraphic system of which we shall all feel proud, which shall abundantly satisfy the public demands, and make it so proper a trust that even the Government will refuse to take it from our control.

We congratulate Gen. Eckert and all his aids on this most successful work.

The War Department, in addition to its weather-signal system, is about to establish an electrical social system of storm signals in all the larger cities of the country, by which every man who is on the magnetic belt can, by watching the signals on his chimney-top or ridge board, tell the moment when it will be safe for him to leave port (or champagne) for home. A black flag flying will signify "cross as a bear—typhoon approaching." A white flag—"everything is lovely; she is asleep." A red flag, with white centre—"look out for squalls; baby just spanked." While a white flag, with red centre, indicates simply "cautionary" measures on the part of the "old man," who can go home under full sail, but should reef his boots and douse the binnacle lamp before going up stairs.—*Titusville Herald.*

The annual meeting of the Nova Scotia Telegraph Company was held January 10th at Halifax, when the state of the lines and the operation of the lease to the Western Union Telegraph Company were reported as satisfactory. Legislative action had been secured to protect Nova Scotia from breach of charter by Dominion Co. The directory of last year was re-elected. Officers will be chosen at a meeting to be held at close of the month.

W. H. WISEWELL.

LONDON, Jan. 1, 1872.

Mr. Cyrus W. Field entertained the members of the Telegraphic Conference assembled in Rome at a banquet given in that city to-night.

There were present in the hall the representatives of twenty-one countries, or six hundred millions of people, and of twenty-six different languages.

Private companies were represented to the amount of 300,000,000 francs.

Mr. Field delivered an eloquent address, in the course of which he invited the members to a reassemblage of the Conference in St. Petersburg in the year 1875.

The other speakers, with Mr. Field, urged the necessity of union and of aid from the governments in the cause of telegraphic communication.

A Telegraph Conference will be held in Naples to-morrow.

A NEW demand having arisen for POPE'S MODERN PRACTICE OF THE TELEGRAPH, the publishers have left copies in our hands to meet orders addressed to us. A copy will be mailed, post paid, on receipt of two dollars.

THE Sioux City and Pacific railroad telegraph office is now in charge of George W. Gardner, aged 11 years, late of Fremont, Nebraska, where he graduated as a first-class operator, after eight months service as messenger boy. Have you any smarter boys than this? If so, trot them out.

Referring to the charge against Mr. Scudamore of stopping Press dispatches in order to crush the recent attempt at a strike among English operators, the London correspondent of the *Tribune*, G. W. S., says:

"A correspondent has brought out the fact that Mr. Scudamore, in recently intercepting telegraphic dispatches, committed an offence not merely against morals and decency but against the law. The Telegraph Act, under which the Government acquired the lines, provided that anybody in the post-office who should, contrary to his duty, disclose or intercept any message, shall be deemed guilty of a misdemeanor, and upon conviction be subject to imprisonment for a term not exceeding 12 months. Under that act I do not see why Mr. Scudamore may not be tried and sent to jail like any other offender. If an officer of a private company had done a like thing, dismissal would have been the certain penalty, and, in so aggravated a case, prosecution would almost certainly have followed. In a government officer the guilt is far greater, but I suppose we must wait till Parliament meets before so much as a complaint would have a chance of being listened to. Possibly somebody may say that Mr. Scudamore, when he read and delayed a newspaper dispatch, was not acting "contrary to his duty," but in pursuance of it. If that is to be the defence, it must be stated in Parliament, and if stated, the Government of which Mr. Scudamore's chief, the Postmaster-General is a member, must either adopt or repudiate it. I will undertake to say that either the Government or any single Minister who ventured to adopt it would be driven out of office with hootings before 24 hours were over. But the fate of Sir James Graham is too fresh in Ministerial minds to permit such a blunder as that. Mr. Scudamore's interference will be disavowed, and I suppose some sort of excuse will be made for keeping him in office."

TRANSFER SERVICE.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY.
145 Broadway, New York,
January 15, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since Jan. 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

241 Adams, Ind.	112 McKee's, Pa.
21 Auburndale, Mass.	112 Martinsburg, Pa.
378 Bowling Green, Ky.	220 Milford, Mich.
357 Cambridge, Ill.	261 Millersburgh, Ind.
298 Chebanse, Ill.	253 No. Bend, Ohio.
336 Dunlap, Ill.	220 Novi, Mich.
85 Ellicott City, Md., re-op'd	119 Pentwater, Mich.
300 Fort Branch, Ind., heretofore an Other Line office.	300 Princetown, Ind., heretofore an Other Line office
* Fullerton, Pa.	300 Patoka, Ind., heretofore an Other Line office.
* Fargo, D. T.	378 Pike, Ill.
112 Henrietta, Pa.	378 Pleasant Hill, Ill.
300 Hazleton, Ind., heretofore an Other Line office.	358 Pearl, Ill.
346 Hampton, Ill.	41 Roselle, N. J.
484 Jewett, Texas.	254 Stanford, Ky.
367 Lost Nation, Iowa.	66 Tuscarora, Pa.
378 Laddonia, Mo.	378 Vandalia, Mo.
119 Ludington, Mich.	220 Wixom, Mich.
119 Manistee, Mich.	336 Wyoming, Ill.
283 McLeod, Ky.	76 Wernersville, Berks Co., Pa.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.	*Leaves this Line.*
Fullerton, Pa.....	15	1 Catasauqua, Pa.
Fargo, D. T.....	230	13 Milwaukee, Wis., check Chicago Ill.

OFFICES CLOSED.

Bastrop, Texas; Brinckley, Ark.; Edgerton, Col.; LaGrange, Texas; Thibode ux, La.; Thompsontown, Pa., and Wilton, Me.

GENERAL INFORMATION.

The tariff to square 119 from squares 297, 306, 307 and 316 will be one dollar; from all others, 20 cents more than to square 269.

The following changes in "tariff for Other Lines" have been authorized: From Plattsmouth, Neb., to Lincoln, Neb., 25 and 2; Columbia, S. C., to Abbeville, S. C., 65 and 4; to Greenville, S. C., 85 and 6, and from Kingsville, S. C., to Camden, S. C., 50 and 3.

The P. O. adds. of Bronsons, Pa., is Shamburg, Pa.

The name of the office heretofore known as American Central Crossing, Ill., has been changed to Alpha, Ill.

The office 59, Rockdale, Pa., in last JOURNAL, is in Delaware Co., Pa.

OFFICES HAVING "SPECIAL SHEET A"

Will check Kingsville, S. C., 10 cents more than "special rate" to Columbia, S. C., and Tuscarora, Pa., 20 cents more than "special rate" to Philadelphia or Harrisburg, Pa.

ATLANTIC CABLE BUSINESS.

We are notified that messages can now be sent to Shanghai and Hong Kong, "via Russia," rate from London $21.50 for 20 words, and half rate for every additional ten or fraction of ten words.

The words "via Russia" must be inserted in the message, but will not be charged for beyond London.

WILLIAM ORTON, President.

A HANDSOME CHRISTMAS PRESENT.

On Monday afternoon Captain N. M. Booth, the worthy Superintendent of the Ohio River Telegraph Line, who had been ill for a day or two, was aroused from an afternoon sleep, and summoned to his parlor, which he found filled with new and elegant furniture, a present from the various operators along the line, who had contributed to its purchase and had it delivered by the operators at the Evansville office. Mr. Duke made the presentation speech in terse but expressive language, to which Mr. Booth, who was taken completely by surprise, responded in as coherent a manner as possible. It was a handsome gift to a most worthy family.

A NEW SYSTEM OF RAILROAD TELEGRAPHIC SIGNALS.

A novel system of telegraphic signals has just been introduced by way of experiment at this end of the Lowell Railroad. At present only East Cambridge is connected with the Boston depot, but if the workings of the new system are found to be successful and satisfactory through the winter months, it may be adopted along the whole line. A box in the train house of the passenger depot on Causeway street is connected by wires with the office of the ticket master, who, when a train starts, by the pressure of a finger upon a little instrument, displays at an aperture in front of the box a red flag if in the day, or if it is at night time the red sides of a lantern to view. When the engine reaches the rail directly in front of the station at East Cambridge the electric current is opened, and the red flag disappears or the lantern shows a white light. A bell is also rung at the same moment in the ticket office. If this system works well, and is adopted along the line generally, it may easily be so perfected that knowledge of the position of a train may be known at any station which it has just left, and thereby insure comparative safety to passengers.—*Boston Herald.*

Sidney E. Morse, a brother of Prof. Samuel F. B. Morse, the inventor of the telegraph, died of paralysis, a few days ago, in New York city, at the age of 77. He was born in Charlestown, Mass., and graduated at Yale at the age of 14. He subsequently studied theology at Andover, Mass., and law at Litchfield, Conn. He edited successively the Boston *Recorder* and New York *Observer*. Mr. Morse was better known by his well known text-book on geography. He was the inventor of the process known as cerography by which maps can be printed on the common printing press. This art was not patented and has never been made public. Since his retirement from journalism, in 1858, he has been engaged with his son upon the invention of the "bathometer," an instrument to be used in making rapid explorations in the depths of the sea. This was exhibited at the Paris Exposition in 1867, and it is believed will prove useful to science.

A PLEASANT GATHERING.

Yesterday was the anniversary of W. C. Buell's departure from the Western Union Telegraph Company, in charge of whose office in this city he spent many years. He left it to engage in what has proved a most successful venture. Accordingly, last evening his insurance and real estate exchange office, No. 265 River street, was the scene of as elegant a spread, surrounded by as jolly a set of guests as can ordinarily be seen by the unassisted vision. At the head of the table sat Mr. Buell, himself, who presided with grace and dignity. His successor in the telegraph office, the new "Boss," Mr. Prescott, was present with all the lightning manipulaters in the vicinity. Mr. Buell's speech upon the occasion was an effort that brought the old times back to the memories of all and renewed in all hearts the old feelings of friendship. Mr. Prescott's responce was equal to the occasion. It would be impossible to give the happy effect of operator F. D. Adam's telling oratory, or the pleasing reminiscences of Ben. Follet and a dozen others in the company. At a seasonable hour in the evening after full justice had been done to the collation and a basket or two of the "best," the party seperated, wishing for "many happy returns of the same."

A LADY PLEADS FOR DECENCY.

Cadiz, O., Jan. 3d, 1872.

To the Editor of the Journal of the Telegraph:

Living all our lives in this quiet little town off the Railroad, connected with the Telegraph world by a single "loop," we know little of the great world beyond, from which we have only an occasional whisper.—Still we fancy this one of its brightest spots.

We learned the business in this office, and during our two years experience have come to think Telegraphers the best people in the world.

Personal acquaintance does not warrant this partiality. We have seen very few indeed, and they speak so pleasantly over the wire, never forgetting common courtesies; that we very naturally supposed them free from the greater faults—*moral* men, at least.

Unhappily we have lately found a few exceptions. While speaking of the unpleasant fact to our neighbor of same craft, he said, "Why they all either drink, use tobacco, or swear—excepting the ladies."

Now can this be possible? These vices are so common, we cannot hope that they have not some votaries among our profession, and can scarcely hope that a word of ours can do anything toward reforming them. Yet we would entreat all to abstain and forsake them. We have a personal concern for the honor of the craft. Personal character is too valuable to be wretchedly yielding to vices so debasing.

Be a *man* my brother; these vices debase you. Its enough to make an angel weep to see those who might made their lives glorious, slaves to these debasing habits.

No step to ruin is more sure than the first, but it is the easiest to retrace.

"Now is the accepted time"—return, and let us have a "Happy New Year." M.

SABBATH REST.

I look upon the Sabbath day as a day of holy, physical, and mental recreation; I look upon it as a day of which you must devote a good part to the worship and service of Almighty God; but I look upon it as a day that yon may devote to many family affections, to many family duties, to social intercourse, to many little innocent enjoyments; and if there is anything on the face of the earth that to my mind is more beautiful than another, it is on the Sabbath day, under the bright sun and on a glowing evening, to see the working man with his wife on his arm and his children behind him, all disporting themselves under the open canopy of heaven. I ask you now to look at this picture. I know we have it in London, and I hope you have it here in Glasgow. Donald going out of an evening, with his Jeannie upon his arm, nice and neat, in her cap and kirtle, and all the bairns round about them enjoying themselves. Then they go home, then they have to examine the Bible, then they read a chapter of the Word of God, then they join in the common prayer, when they retire to bed, and Donald rises next day and resumes his working clothes, full of confidence and joy, because he knows that he has spent well the Sabbath, and that God will be with him for the ensuing week. It is impossible, in looking over the old race of human life—it is impossible for those who will be candid to admit the truth for them not to see and confess the wisdom of the Sabbath, of the institution of the Lord's day. A rest of one day in seven is so necessary, so true, and so wise, that it could not possibly have sprung from any human origin, but must have come down as a revelation, an ordinance from heaven. Those who are most engaged in works of toil, whether it be of the brain or of the hand, call out for repose, and if it be said that rest is necessary to the human mind and the human body, I ask you if there ever was a period in the history of the world, in the history of this nation, when it was more necessary than at the present moment! Is it not an observation of every one that we are living with immense rapidity? Is it not an observation of every one that we are crowding into a year the events of a century? Is it not an observation of every one that the mad competition of trade keeps every one upon tenter hooks, keeps every one in the furnace, keeps every one in such a state of excitement that the nervous system is shaken? Everybody knows that in the days in which we live, the moral system, the intellectual system, is more greatly disturbed than ever, owing to the wild competition in every department of trade and art in which men's minds are so buily engaged.—*Lords Shaftesbury at Glasgow.*

Russian Telegraphy.—In consequence of the new telegraphic treaty between Russia and Persia, preparations are being made for the erection of a number of new lines of telegraph. The lines, radiating from a central station at Astrakan, will skirt the Lower Volga and the Caspian Sea.

BORN.

In Pittsfield, Mass., Jan 3d, a daughter to F. M. Marsh, Line Repairer, W. U. Telegraph Co.

A young operator here born to S. O. Campbell, operator, Centretown, Cole Co., Me., a daughter, weight, eleven pounds, December 10, 1871.

To Herbert J. Bresee, manager W. U. Telegraph Office, Suspension Bridge, N. Y., Dec. 29, a son, "first rooster."

MARRIED.

Arbuckle—Swift—At the residence of Mr. H. Wentworth, Christmas Eve., Dec. 24, by the Rev. R. H. Annis, Mr. Frank P. Arbuckle, Agent and operator, Kansas Pacific R. R., Fossit, Ks., to Miss Emma A. Swift, of Fond-du-Lac, Wis.

Hunter—Woolsey—Dec. 20, 1871, at the residence of the bride's father, in Sandusky, Ohio, Mr. J. W. Hunter, manager, W. U. Telegraph Office, at the above place, to Miss Nellie Woolsey.

Rebhun—Lovell—Dec. 5, 1871, at Bunnington Furnace, Pa., by the Rev. N. F. King, of Hollidaysburg, Pa., Chas. Rebhun, manager, W. U. Telegraph Co., Butler, Pa., to Miss Ellie M. Lovell, both of Butler.

Page—Jackson.—Tuesday, January 2d, at Red Bank, N. J., by the Rev. Wm. N. Dunnell, Harry W. Page, of Shiloh, O., operator at Red Bank, to Florence J. Jackson, of Red Bank.

Foster—Van Horne.—At Odell, January 1st, 1872, by Rev. C. J. Collins, Chas. E. Foster, operator C. A. & St. L. Ry. telegraph, to Miss May Ella Van Horne, only daughter of Hon. J. R. Van Horne, of Lockport, Ill.

Skeggs—Mills—At the residence of the brides father, January 3rd, 1872, by the Rev. Edward Torrance. C. B. Skeggs, manager, W. U. Telegraph office, Jonesboro, Ill., to Miss Jennie Mills of Horrodsburg, Ky.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 5. NEW YORK, FEBRUARY 1, 1872. WHOLE NO. 102.

EUROPEAN SALARIES.

The following are official statements of the salaries paid to the officers and employes of the telegraph service in several European countries. We have failed to obtain the rates of compensation in Great Britain in authentic form, and for that reason omit them altogether:

FRANCE.

General Superintendents	$2,400	per annum.
Division " 1st class	2,000	"
" " 2d "	1,800	"
Managers of offices, 1st class	560	"
" " 2d "	520	"
Principal Clerks	500	"
Operators, 1st class	480	"
" 2d "	420	"
" 3d "	360	"
" 4th "	320	"
" 5th "	280	"

SWITZERLAND,

Superintendent	$900	per annum
1st Secretary	600	"
2d "	500	"
Auditor	600	"
1st Assistant Auditor	480	"
2d " "	360	"
4 Inspectors	$540 to 720	"
Managers of Offices	360 to 600	"
Operators, 1st class	480	"
" 2d "	420	"
" 3d "	360	"
" 4th "	320	"

PORTUGAL.

Director-General	$1,500	per annum.
Inspector	1,100	"
Superintendents	500	"
Office Managers, 1st class	450	"
" " 2d "	360	"
Operators, 1st class	300	"
" 2d "	240	"
" 3d "	200	"
" 4th "	150	"
" 5th "	125	"
Line Repairers, 1st class	100	"
" 2d "	80	"

ITALY.

Chief Inspector	$1,200	per annum.
Sub-Inspector	800	"
Directors of 1st class	1,100	"
" 2d "	900	"
Chiefs of Section of 1st class	600	"
" " 2d "	560	"
Operators, 1st class	440	"
" 2d "	400	"
" 3d "	360	"
" 4th "	300	"
" 5th "	240	"

BAVARIA.

The average compensation per year is as follows:

For the assistants—First three years	$172	
" " After " "	189	
" " " six "	236	
" " " twelve years	268	
" Telegraphists—First three "	193	
" " After " "	286	
" " " six "	300	
" " " twelve "	364	
" Chief " First six "	386	
" " " After " "	429	
" " " " twelve "	472	
" " " " eighteen "	514	

TELEGRAPH BUYING.

[From the N. Y. Tribune.]

COMPETITION IN TELEGRAPHY.

The Gov't has a monopoly of Mail-carrying; the Western Union is exposed to competition in Telegraphing from every side. If you want to dip into *their* business, there is nothing in the way but an aching void, present or prospective, in your own pockets; if you interfere with the Govt.'s monopoly of letter-carrying, you do it at your peril. The Govt. pays nothing for the blunders or peculations of its mail-handlers; it may damage you $100,000 to-morrow through the loss or non-delivery of your letters, and it laughs at your petition for redress: the Western Union must pay for every blunder or error, no matter how innocent, so that the father of a girl at boarding school, who lately received a dispatch from the principal which read, "Your daughter had a child last night" (when it should have read *chill*,) made the Co. pay smartly for the operator's error. Just fancy that father applying to the Postmaster General for smart-money in such a case, and imagine the horse laugh which would be the only response.

When we shall have so reformed our Civil Service that every tide-waiter and letter-carrier shall not be expected to loose his place at each turn of the party wheel, and every third youth in the land shall not be looking to office as his way to subsistence and competence, we may think of enlarging the area of Govt. intermeddling with business.

THE EXAMPLE OF ENGLAND.

[From the Detroit Free Press.]

About the only thing adduced in its support is the statement that it would be a very good thing for the people to be able to send messages at a slight cost; and then we are told that the system works well in England, as if that made any material difference with us.

When we consider that the United Kingdom has altogether but 120,000 square miles—about equal to two States the size of Mich., with twenty-five times the population of our State—that the Postal Dept. of the Govt. there is selfsustaining, and that there is scarcely a quarter of the telegraphic business done in that country that there is here, and that most of the post-offices—and now also telegraph stations—there are in cities of comparatively large size, while here every village of a thousand inhabitants has a post-office, and would be entitled to a telegraph, it will be seen that there is

NO ANALOGY BETWEEN THE TWO COUNTRIES.

In England, too, there is not the same disposition to attack public men as there is in this country, and State secrets are much more closely guarded. The press, in the matter of news does not show anything like the enterprise of the American press, and the telegraph is not nearly as much used by them. In this country were there a postal telegraph line established, there would necessarily have to be private lines as well, for no one would feel safe in sending, through the hands of employes of the Govt. dispatches attacking their official superiors. Who supposes that, were all the wires under the control of the government, the N. Y. *Tribune*, and the press of the country at large, would have been able to publish the text of the Washington treaty at the time they did? But, unless the government had complete control of all lines, there would be little use of the scheme.

But in comparing Great Britain and the United States there is another point to be considered. There all appointments are non-partisan, officials not being indebted for their tenure of office to the will of an Executive, or of partisan majority in the legislature. Here all of the thousands of men given official positions by an arrangement such as that advocated by the P. M. Gen. would obtain their appointments more on account of their partisanship than for any other reason. Once appointed, it would be their constant aim and endeavor to keep in power the administration to which they were indebted for their places.

It should not receive consideration because it is a scheme which will only have the effect of

ADDING TO THE BURDENS OF THE NATION

without any adequate return. The present telegraph Co's lines would have to be purchased at an enormous cost, or new ones erected. The telegraph being under the direct supervision of the Govt., demands would come from the extension of the lines into almost every nook and corner of the country; and these demands would have to be acceded to. It is estimated that the first cost of buying the lines now existing and of erecting the new ones desired would approximate $70,000,000, while the Govt. would have to employ from 10,000 to 25,000 operators at a frightful annual aggregate of expense. Our P. O. at present does not pay expenses. Can it be expected that a postal telegraph would be anything like selfsustaining? The telegraph business at present pays, but lines are only extended where there is considerable occasion for their use, and the tariff of charges is so arranged as to make it profitable. A postal telegraph in our widely expanded and sparsely settled country would be a charge on the people of millions of dollars annually.

RAILROAD WIRES; THEIR USES AND ABUSES.

An article, entitled "Railroad Wires; their Uses d Abuses," signed "Observer," in your issue of ec. 15th, has been read by me with interest. Will "Observer" kindly be a little more plain in his explanation of how to remedy what he calls "a very common abuse"—the repeating of train orders? I am open to conviction, and ready to adopt improvements, but I can't yet understand that the way proposed is an improvement. I have been a train dispatcher four years, and have examined several systems, but the only *safe* one I have seen is that in almost universal use of having a message repeated from the conductor and engineer of the train to whom it is addressed. Let us suppose two trains, approaching each other, are three or four stations apart, and it is necessary to hold the one having the right to track till the other arrives; by "Observer's" plan, the orders are sent to both trains at once; the one giving the train a right to go ahead is delivered *O K*, and the other, either through carelessness, neglect, or some other cause, is not; the consequence is a collision, and probable loss of life and property, all of which would have been prevented had the message been first given to the train having the right of track, and then, after receiving their reply saying they understand the order, the message given to the other train to go ahead. Is not a little crowding of wires, a little delay of business, a little vexation and worry far preferable, when combined with safety, to their absence, and a chance of accident? However, as I said before, I am open to conviction, and would be glad to find a remedy for what I must acknowledge to be unpleasant condition of things. Will "Observer" name some road where this "primitive usage" and "very common abuse" has "been abandoned long since," that I may open a correspondence with the train dispatcher, and improve myself in that branch of my business?

T. D.

ANOTHER ON THE SAME SUBJECT.

To the Editor of the Journal of the Telegraph.

Being a constant reader of the JOURNAL, we noticed in your last issue an article referring to railroad wires and their abuses, signed "Observer." Having had a little to do in connection with railroad wires, we are also acquainted with the general mode of sending train orders. Now, we are in favor of improvements, and would be very glad to hear of some method by which the labor and the time consumed in sending train orders might be lessened, but we are afraid "Observer's" plan would hardly "work" in all cases. In some cases it is true one order might be made to answer for two trains, but it is necessary, in order to insure safety, to receive the "32" message from the train which has the right of the road before the order is given to the other train.

Besides, in most cases, there are parts to be inserted in the order for one train that do not refer in the least to the other; therefore we cannot see but it would in most cases make the orders long and tedious enough to more than occupy the time used for two orders.

Yours truly,

ANOTHER "OBSERVER."

STILL ANOTHER.

BURE, January 2, 1872.

To the Editor Journal of the Telegraph:

SIR:—In No. 99 of the JOURNAL I notice an article by "Observer," in which he charges that the manner of sending train orders, as it is generally done, is one of the abuses of railroad wires. His remedy for the abuse, is to make "one order answer for the two trains, by calling up both offices and having them copy at same time." This is a brilliant idea, and reflects great credit upon "Observer." As he seems to know how it is himself, will he please explain how he succeeds in putting the two following orders into one, so that it will answer for both trains.

(1.) To "*Opr. A. Hold No. 1 for No. 2.*"

(2.) To "*Condr. and Engineer, No. 2, B. Run to A, regardless of No. 1.*"

I hope "Observer" will give full details of the system of train dispatching used on the roads that have abandoned, the primitive custom of "first giving an order to one train and then sending another order to the other train." Verdantly yours,

GREEN FLAG.

ACTION OF MAGNETISM ON GAS.

De La Rive and Sarasin have recently laid before a scientific society of Geneva, Switzerland, an important communication, in which they arrived at the following conclusions:—1. The action of magnetism, when only exercised upon a part of an electric jet, projected through a rarified gas, causes an increase of density. 2. The same action on an electric jet placed equatorially between the poles of an electro-magnet produces in a rarefied gas an increase of resistance, which is greater in proportion to the conductivity of the gas. 3. The same action creates a decrease of resistance, when the jet is directed in the line of the axis between the magnetic poles. 4. When the magnetic action consists in the impression of a continued movement of rotation of the electric jet, this action has no influence upon the resistance, if the rotation is in a plane perpendicular to the axis of the cylinder of magnetized iron which determines the rotation; whereas, the resistance decreases considerably if the rotation takes place so that the electric jet describes a cylinder of revolution about the axis. 5. These several effects cannot be attributed to a variation of density produced by the action of magnetism on the gas, but probaby they are explained by the perturbation that such action causes in the molecular arrangement and disposition of the particles of the rarefied gas necessary for the propagation of electricity.

MANY years ago, Professor Edmund Davy, of Dublin, devised 'a simple electro-chemical method of ascertaining the presence of different metals; applied to detect minute quantities of metallic poisons,' which is well worth recalling to notice. He employed a voltaic arrangement of small slips of zinc and platina, placed in contact, and forming a galvanic circuit with the interposed fluid suspected to contain the poisonous metal. In the action thereby set up, the poison was deposited in the form of crystals on the negative surface of the slips of metal; arsenic could be detected if only the five hundredth part of a grain were deposited; and Professor Davy has recorded that in some instances he could appreciate the two thousand five hundredth part of a grain by the application of appropriate tests.

Another advantage of this method is, that these minute quantities can be detected even when mixed with ordinary articles of diet, such as wheaten flour, bread, starch, rice, potatoes, sugar, vinegar, eggs, gelatine, gruel, various kinds of wine; and also in the saliva and bile Besides arsenic, Professor Davy experimented with corrosive sublimate, acetate of lead, and sulphate of copper, and always with the same satisfactory result. In some instances where the common tests failed to act, or only acted fallaciously, he found the electro-chemical method act with the greatest certainty,

THE POWER OF LIGHTNING.

The concentration of power in a stroke of lightning, acting through an inconceivable small interval of time, may perhaps be realized after examining its work of destruction, yet its inductive action on the earth's surface is not less wonderful. Prof. A. M. Mayer made an experiment, some time since, which demonstrated the extent of this action. He connected the wire of a galvanometer with the water-pipes of Baltimore, Md., and joined the other end of the coil to a gas-pipe of a house in the south-western part of the city. Thus a vast metallic system of electric nerves stretched three miles towards the north-west, to the reservoir, and about as many miles to the east and south-east, over the city. A thunder-storm was raging at the time in the north, at so great a distance that only the illumination of the clouds told when a flash occurred. Yet whenever that flash took place, the needle of the galvanometer was instantly deflected through ten or twenty degrees. So nearly simultaneous were the two occurrences that no difference in the instant of their manifestation could be detected. Shutting himself up in a dark room containing the galvanometer, he signalled, when the needle moved, to an observer of the storm, who also gave a signal whenever a flash occurred; and the exchange of signals was always found to be simultaneous. It was ascertained on the following day that the storm was more than twelve miles distant, thus showing that over 500 square miles of earth's surface was effected at each flash of the ligtning.

THERE is nothing that more distinctly marks the progress of the age than the rapidity with which the electric telegraph lines are being carried through the indolent States of the South American continent, thus extirpating the antiquated ideas implanted years ago by the Spanish and Portuguese adventurers, and which for centuries have been so zealously sustained under the powerful protection of the followers of Loyola. In no portion of the Southern continent is this distinctive feature of modern progress more notable than in the Empire of Brazil, whose liberal-minded sovereign has ever been a firm friend of progress. Brazil has as yet, however, but nine hundred and fifty American miles of telegraphic wire, exclusive of the wires of the different railways; but there are many lines being erected, one of which, 1,060 miles in length, will shortly unite Rio de Janeiro with Pernambuco. Still there is a field for telegraphic enterprise yet open in the dominions of Don Pedro, and extensive contracts are daily made with large European and American capitalists. The territory is so vast that, so far, Brazil has only been able to construct one league of telegraph line for each square of one thousand leagues of territory. But Brazil is far outstripping her sister States, and before very long all her principal cities will be in telegraphic communication. It is the boast of the Emperor of Brazil that his reign shall see his country rival the great Republic of the North.—*N. Y. Times.*

PEOPLE who are willing to sleep shut up like a jack knife will be delighted to know of a new process of insuring longevity. A California scientist, whose head like his back must be a trifle weak, declares that he has prolonged his life by sleeping with his finger tips touching his toes, and has invented a machine to hold the body in that graceful and pleasant position. He contends that the "vital electric currents are thus kept in even circumflow, instead of being thrown off at the extremities and wasted." There is no patent upon the great discovery, and any one with a sufficiently supple back, is, of course, free to try the experiment.

CONCERNING the late storm on the Kansas Pacific, a Kansas paper says that the telegraph poles were blown across the track for miles, the wires becoming entangled with the engine and wheels of the train, and the engineer and fireman driven from their posts. Whole herds of buffalo crowded around the cars seeking shelter from the storm.

A COMPENSATING COMPASS.

M. Arson, engineer to the Parisian Gas Company, has just invented a compensating apparatus for correcting the deviation of the Compass. The needle of course does not in general indicate the position of the magnetic north. It is affected by the masses of iron entering into the construction, the armament, or the cargo of the ship. These deviations, which were very feeble in the time of wooden sailing vessels, have become more and more considerable in proportion as iron has been more largely used in the hulls of ships, as powerful engines and boilers have been introduced, as armor plates of ever-increasing thickness have been added to the sides of vessels, and as iron has been utilized for masts and rigging. There are cases were the magnetic influence of the ship so overbalances that of the earth, that although the position of the compass is chosen with the greatest care, it is impossible to obtain much information from its indications.

The means most generally employed to escape this inconvenience consist in checking the deviation of the needle by the influence of the ship, and preparing either tables of corrections or a curve, called Napier's curve, the inspection of which allows the deduction of the true from the observed variations. This estimation of deviation entails a rather long and delicate operation, which, moreover, has to be repeated for different latitudes, to allow for the alterations of magnetic influence.

The mathematical works of Poisson and of Airy have furnished, it is true, analyses of complicated magnetic phenomena, and many investigators have proposed means of compensating the deviating influences. But navigators have shown in general little confidence in these various systems, because all would require frequent changes in the position of the magnets, or of the masses of iron which serve for compensation; and these changes involve operations so delicate, and an incertitude so great, that it is preferred to put confidence in a compass which is supposed to be compensated, and which is more or less true.

The masses of iron in a ship act in two manners on the needle of the compass—first by their permanent magnetism, and then by the induced magnetism that they take under the influence of the earth. The first effect is constant, and comparatively easy to subdue. The second varies with the position of the ship, and can be compensated only by a movable needle.

The uncertainty of the moving compensators involves, in the port of departure, the correction of the deviation of the compass by a magnet, as far as possible, then ascertaining by direct observation the remaining deviations, in order to place their quantity on the table or on the curves of correction. At present this is the general practice in the navy.

M. Arson hopes by this arrangement to obtain exact compensation. Fixed magnets compensate the deviations due to the permanent magnetism. Bundles of soft iron wire placed according to certain laws given by calculations, ought to compensate the deviations caused by induced magnetism in all positions of the ship and in all latitudes. The proposed apparatus, which has already been applied on one of the steamers of the Transatlantic Company, contains, besides the ordinary card, a second card, serving as an indicator. When it is wished to follow a given route, this latter card is traced by means of a wheel until it indicates the desired angle. Now, by this movement the operator has placed the packets of soft iron into the position in which they are required to compensate for the deviation corresponding to the position of the ship. It is sufficient then to adjust the needle of the compass to the same angle which has been given, in order that the route indicated may be actually followed.

Conversely, if it be wished to ascertain at any moment the route which the ship follows, it can be done by moving the wheel before-mentioned until the repeating circle indicates the same angle as the compass. By this movement the compensating parts will have been placed in the position which corresponds to the compensation in he azimuth where the vessel is; the angle observed will be the true angle of the route.—*English Paper.*

THE ACTION OF DILUTE SULPHURIC ACID ON AMALGAMATED ZINC.

It is commonly supposed that the action of dilute sulphuric acid on the amalgamated zinc used for the negative metal in a galvanic battery entirely ceases when the battery is not in action. This, however, is not the case, as a slow decomposition continually goes on, and it will be found that in a day or two the surface of the zinc will become covered with a thick layer of a spongy amalgam of the mercury and zinc, which increases day by day, and, if the battery be a Daniell, will soon attach itself to the porous diaphragm, and, decomposing the cupric sulphate, soon cause the battery to cease working. When, however, it is only required to use the battery for a few hours, the amalgamation of the zinc is very beneficial, as it preserves the surface of the zinc bright, but it does not increase the electro-motive force, as is sometimes supposed.

M. Th. Du Moncel, in the *Comptes Rendus*, t. lxiii. p. 436, in an elaborate memoir, shows that, by increasing the size of the electro-positive plate of the voltaic battery, the intensity of the current is not affected if the resistance be great; but in a circuit of small resistance the resistance of the battery cannot be neglected. When the size of the electro-negative plate is increased, the permanency of the battery is decidedly greater; there is also greater economy of zinc, and the intensity, contrary to his expectation, in no way diminished.

PHYSIOLOGICAL EFFECTS OF LIGHTNING.

The New York *Medical Journal* has an interesting paper on the physiological effects of lightning, from which we gather the following statement:

"A thunder-bolt has been seen," says Barbaret, "to split a tree without even blackening it, while it *reduced to ashes* a shepherd who had taken refuge under its branches." . . . "One man alone was killed," says Abbé Richard, "and *almost reduced to dust*, in the midst of many others who were under the same tree." . . . "The most curious as well as the most recent instance is the following: At Vic-sur-Aisne, in 1838, a thunder-bolt struck a lime-tree, under which three soldiers had taken shelter; they were all killed at the same instant; still, although lifeless, the three *remained erect*, as if the electric fluid had not reached them, their clothing also appearing uninjured. But when they were touched, all fell, so it is said, into a *heap of ashes*."

Colonne says: "The fire of exhaltation which forms the thunder-bolt must be so subtle and penetrating, that it kills a man by drying up instantaneously all his humors, without in the least changing his figure. We do not perceive him dead until we *touch* him, and then *we see him fall to dust*."..... Gronberg remarks: "It is demonstrated that lightning reduces bones to *ashes*, but never to the state of fusion." Izarn observes: "It is proved that lightning reduces bones to ashes." In fine, Abbé Mann asserts: "Lightning reduces to ashes all parts of the human body, without altering the clothes or skin."

Besides the complete incineration of persons, or of portions of bone, and of trees struck by lightning, we have also found that of some inorganic bodies, such as the following: a lady's *bonnet*, a man's *shoe*, except the wooden sole; *panes of glass* in windows; a *cloth* covering shields which were fused; a *purse*, the gold and silver which it contained not being damaged; the *scabbard* of a sword; a large *beam* reduced to dust in the middle of a chamber closed and fastened on all sides, without any injury to the chamber; the different *materials* of a house destroyed by lightning; the wood of a *cask*, etc.

General Comte de Maistre, son of the illustrious author of *Soirees de Saint-Pétersburg*, informs Dr. Boudin that some Sardinian sailors killed by lightning in the Mediterranean presented all the signs of death by *freezing*. "This observation is the more remarkable," adds M. Boudin, "as it recalls the congelation of wine long ago noticed by the ancients." On a man struck by lightning toward the back of the head, at the passage of the stroke, there could be found neither fracture or fissure, nor yet an alteration in any other part of the skull. The brain was also very sound, there being alone at the superior part *congealed lymph*, which had infiltrated in the folds of the *pia mater*. This young man, killed by the stroke remained *immobile*.

The following theory is proposed as an explanation of this curious fact:

The recent researches of MM. Joule, Clausius, Thomson, and others, have led physicists to regard heat as resulting from a rotary motion of particles about a axis, and M. de la Rive has considered this hypothesis as calculated to explain the polarity of atoms. This *savant* then asks, "if it might not be possible that the cause of the heat generated by the reunion of the two electricities, brought about under the form of discharge of current, may be, not in the fact itself of this reunion, but in an increase of molecular motion, which might result from the transmission of electricity?" Consequently, according to this theory, a current or an electrical discharge directed upon a body, must give rise to two molecular motions in contrary directions, and in the sequel to effects equally inverse. In the first case, the current being directed *in the same way* as the polarity which produces the natural heat of the body, it is evident that it augments the rotary motion of the particles around their axes, raises their temperature, and produces in proportion to its energy new thermo-mechanical effects. The result, therefore, will be the elevation of the temperature of the body traversed by the current of electrical discharge. In the second case, the current being, on the contrary, *in an inverse direction* from the polarity which produces the natural heat of the body, it is also evident that it diminishes the rotary motion of the particles around their axes, lowers the temperature, and produces, as in the first case, thermo-mechanical effects proportional to its power. The result will therefore be a lowering instead of an elevation of the temperature, which lowering may descend to the freezing-point.

The London *Illustrated Times* says: "By the way, speaking of water-proofs, I think I can give travelers a valuable hint or two. For many years I have worn India-rubber water-proofs, but I will do so no more; for I have learned that good Scotch tweed can be rendered utterly impervious to rain, and moreover, I have learned how to make it so, and for the benefit of my readers, I will give the receipt: In a bucket of water put a half pound of powdered alum; then stir this at intervals until it becomes clear; then pour it off into another bucket and put the garment therein, and let it remain for twenty-four hours, and then hang it out to dry without wringing it. Two of my party, a lady and a gentleman, have worn garments thus treated, in the wildest storms of wind and rain without getting wet. The rain hangs upon the cloth in globules. In short, they were really water-proof. The gentleman, a fortnight ago, walked nine miles in a storm of wind and rain, such as you rarely see in the south; and when he slipped off his overcoat his under clothes were as dry as when he put them on. This is, I think, a secret worth knowing, for if cloth can be made to keep out wet, it is in every way better than what we know as water-proofs.

THE FRANKLIN STATUE.

The erection of the statue of Benjamin Franklin in Franklin Square, New York, and its inauguration on the anniversary of his birth-day, January 17th, is so identified with the erection of the Morse statue in June last that we deem it proper that a record of it be preserved. Independent, indeed, of any such connection, there must ever be associated in the minds of men throughout all time a relationship between Benjamin Franklin and the lightning, which properly identifies his name with the telegraph, "the last best gift of science to the world." The statue itself is of colossal size, and is the gift to New York of Mr. Albert DeGroot.

The ceremonies commenced at noon, and after prayer by Rev. Dr. Deems, Douglas Taylor, Chairman of the Committee of Arrangements, introduced Prof. Morse, saying: "This distinguished inventor and pride of our country will now unvail the statue of Franklin."

PROF. MORSE'S REMARKS.

Mr. De Groot and Fellow-Citizens: I esteem it one of my highest honors that I should have been designated to perform the office of unvailing this day the fine statue of our illustrious and immortal Franklin. When requested to accept this duty I was confined to my bed; but I could not refuse, and I said yes, if I had to be lifted to the spot. Franklin needs no eulogy from me. No one has more reason to venerate his name than myself. May his illustrious example of devotion to the interest of universal humanity be the seed of further fruit for the good of the world.

At the close of his remarks, Prof. Morse removed the streamer by which the folds of the flag covering the statue were kept in position, and the massive figure suddenly appeared to view, amid the loud cheering of the crowd, music by the band, and a salute from a cannon in the Park. Prof. Morse then retired to the *Tribune* office, being greeted on his departure with hearty cheers.

Hon. Horace Greeley was then introduced, and presented the statue to New York.

MR. GREELEY'S ADDRESS.

I rejoice that this work is, like its subject, purely American. It may be that European art is able at this stage to have produced a better one—though I think not. [Laughter.] But, at all events, the production of this is our warrant for believing that if better statues can be created, we have by this example—by this achievement—prepared our countrymen to produce them in a future not distant. [Applause.] I rejoice, fellow-citizens, that, while presenting an American statue of an American philosopher, the gift of a public-spirited American citizen, we have been assisted to-day in inaugurating this statue by that eminent American discoverer, who to-day is the nearest resemblance to the great and patriotic citizen whose memory we all honor. I rejoice that Prof. Morse—born in that very city of Boston, within rifle-shot of Franklin's birth-place, and the year after Franklin died, and who seems to have been raised up by Providence to be the continuer of that great work of which Franklin was the beginner—I rejoice that he has been spared to meet with us on this interesting occasion. This man seems to me to be the proper successor of Franklin; the one taught the world how to tame the lightning, and the other has taught us how to render it most useful as a messenger of intelligence across continents and oceans; so that to-day, by the invention of Morse, the whole world is placed in instantaneous communication, and any interesting event is flashed as by the lightning from one end of the habitable globe to the other. So I may say, fellow-citizens, in honor of Franklin, and I may also say in honor of Morse, I present, in behalf of Capt. De Groot, this statue of our great exemplar to our intelligent and, I trust, appreciative profession.

After another air by the band, the following address of acceptance was made by C. C. Savage, President of the Board of Trustees of the New York Typographical Society:

ADDRESS BY MR. SAVAGE.

Albert De Groot and Gentlemen of the Press: It is appropriate that this statue should be erected in this centre of our trade, in the very midst of our craft work, instead of in Central Park; for Franklin's life was devoted to practical hard work, rather than to the ornamental and the recreative. Could Franklin step into the mammoth printing and newspaper offices which surround this monument—could he look into yonder Post Office—what thoughts and contrasts would they suggest? I would remind you of Franklin's habits of industry and frugality whereby he early acquired ease in business and wealth; of his unswerving integrity, which secured him the steadfast confidence of his countrymen; of his fidelity and patriotism, which brought him the highest honors and offices in the gift of his country; of his sagacity and justice, which enabled him to cope with and master the most astute statesmen of Europe; of his studiousness and research, which gave him the key to unlock the Divine Arcana, and present to the world priceless treasures; and of his temperance, which preserved a sound mind in a healthy body for more than four-score years. In a word, Franklin was ever diligent in whatever department he labored, to leave it better than he found it; and he stamped the whole with the simplicity, genius and grandeur of his unaffected manhood. Surely, such a man is a co-worker with the Deity, to uplift humanity, and bring the race nearer to freedom, to brotherhood, and to God.

Prof. Morse, we welcome your participation in this scene; for no hand was deemed so worthy to lift the vail as yours. Franklin caught the electric thought from heaven; but it was reserved for you to yoke its untamed power to the service of industry and intelligence. Wherever the iron nerves traverse the earth, there will be known and linked the names of Franklin and Morse.

Albert De Groot, we thankfully receive this deed of trust from your hands, and we pledge ourselves and our successors to guard it with the vigilance of love. May God bless you for your noble gift!

THE BANQUET.

A grand banquet was given in the evening, which was attended by a number of distinguished gentlemen, in the list of whom we notice the President of the Western Union Telegraph Company.

A number of spirited speeches were made, chief among which were those of Dr. Prime, Rev. Henry Ward Beecher, and Mayor Hall. We have only space for that of the latter gentleman.

MAYOR HALL'S SPEECH.

I take the reception you have given me as a proof that you will not discharge an old compositor because his types get mixed [laughter], or because he slipped while the devil was running away with his copy. To-day the city which you have toasted beheld Franklin's statue unvailed. Last summer she witnessed the dedication of another to Morse. The first one faces the newspaper temples wherein public opinion finds shrines. The other confronts newspaper readers who daily throng Central Park; from the skating newsboy to the sauntering student. But why these statues in this antithetical attitude? Is it not that the distance between the down-town statue and the up-town one—at topographical points that also mark the material growth of the city from the era at which Franklin died to the epoch in which Morse still honorably survives—that this distance may represent the intervening and crowded space in history between the first and freest ally of newspaper enterprise; or between the hand printing press and the electric telegraph—between the lightning experiments of Franklin and the electric utilizations of Morse? The presence of these two statues in this crowded metropolis will ever emphasize an old text, and indeed paraphrase it—He who runneth may read, thrilling references to the march of human intelligence.

The spectacle this day witnessed in Printing House Square will become historical in the annals of the State and city—Morse unvailing the statue of Franklin! It was as if Herschel had dedicated a monument to Copernicus, or Robert Hoe one to Caxton, or Faraday another to Roger Bacon, or Mr. Beecher one to St. Paul.

THE CALLAUD BATTERY.

A record of 80 cups Callaud local battery for the month of December, 1871, shows the consumption of sulphate of copper to have been 16½ ounces per cup for the month, the circuits being in use in the day time and about half of the night.

A record of 200 cups of Callaud local, for the month of November previous, shows an average consumption of 22½ ounces per cup for the month. The largest amount consumed by a single cell within one month, of which we have a record, is 28 ounces, the circuit been closed night and day on a local sounder, with a resistance of 2 ohms. The average resistance of the cell 2¾ ohms.

A record of 36 cells main battery on a line five miles long with three instruments shows a consumption of sulphate of copper of 5$\frac{3}{16}$ ounces for the month of December. The circuit was closed during the day and generally during the night.

A record of 15 cells battery on a line one mile long with two instruments show a consumption of 6 ounces per month, per cell.

The average resistence, 63 cups Callaud main battery, was 4 ohms. That of the same number of Daniell main cups was 3½ ohms.

The consumption of zinc was in proportion to that of vitriol, the average being about 4 ounces per cup, per month.

The above maximum of consumption shows this battery to be as cheap in maintenance as any in the material consumed for the work done.

Add to this consideration the fact that the Calland battery maintains its constancy for a much longer period than any other, and that the labor of maintenance is almost nothing, and we see the reason why it is being so commonly adopted in this country as well as Europe.

INTERPRETING THE RULES.

There seems no apology for the construction of the rules indicated by the following message from W. Albany, N. Y., to Buffalo.

To ——

Buy as soon as you can, and ship if you find kind I want. 14. paid. Signed ——

Answer if you buy.

The postcript was sent, as will be seen, free. It is difficult to tell why. No rule warrants it. It should have been inserted in the body of the message and charged 18 words.

THE TELEGRAPH CONGRESS.

THE COLISEUM ILLUMINATED.

Telegram to the New York Herald.

ROME, Jan. 15, 1872.

The convention adopted by the International Telegraph Congress has been signed and the delegates have gone home.

CIVIC HONOR TO THE REPRESENTATIVES OF PROGRESS.

The illumination of the Coliseum in honor of the Telegraphic Congress was most successful. An enormous crowd of people were present to witness the spectacle, which was most magnificent. At a given signal the whole of the majestic ruins were bathed in a sea of light, the spectators remaining to the last. Before the crowd had time to disperse finally three rockets fired in the air announced another phase of the spectacle, and instantly the whole of the edifice was again illuminated, but this time each row of the extensive galleries displayed a different color. The persons who had assembled to witness the display then dispersed, highly gratified by the spectacle.

*Dead.

AN ANXIOUS MAN.

TOLEDO, Ohio, Jan. 1st, 1872.

DEAR SIR :—I have heard much in regard to the Automatic Telegraph Company of New York.

Now I am practicing telegraphing at the W. U. Telegraphing Office in this place and am about half through with the course. I have paid half the tuition, the remainder is due soon, but if this Automatic Company can do all they claim I will give it up before I pay the remainder, as many operators will in time be thrown out of employment and, of course, there will be no chance for new or inexperienced operators as this system must become obsolete.

This new company claim they can send from 500 to 1500 words per minute, and at a cost of not more than 25 cents per fifty words from New York to Chicago, or can when under good head-way.

Now, you must know something about this company, whether they can do what they claim or whether there is some draw back that will prevent its going into universal use. Will you give me your opinion as to whether it would be best for me to complete my course, and do you think there are still chances for good operators, by the Morse system, in the West. A STUDENT.

Answer.—Better finish your course. Automatics are as yet in a very infantile condition. The Morse system shows no signs of any early death.

MIDDLETOWN, Jan. 9th, 1872.

To the Editor of the Journal of the Telegraph:

As in our business there are many operators that seem to circulate, and the principal portion of the manipulating force are young men, it would be an advantage to all to have a protecting society under the auspices of the W. U. Company, having examiners as the public schools have, in some places, who will give the persons passing examination a graded certificate of ability. As each operator would want a certificate, an income sufficient to pay expenses could be easily obtained. Cannot some one originate the society in fact, as it has long been originated in theory. It could be much easier carried on in our occupation than almost any other.

OPERATOR.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JAMES D. REID, Editor,
Executive Rooms, Western Union Tel. Co.,
145 Broadway, New York.

NEW YORK, FEBRUARY 1, 1872.

TELEGRAPHIC MONEY ORDERS.

For the last twenty years, indeed, ever since the Telegraph offices were first opened to the public, there has been an instinctive perception of the use of the Telegraph in the quick provision of money at distant points, to meet special emergencies. A stranger in a city finds himself without means; a word to a friend or partner in a neighboring or distant city, would secure a speedy remittance. Cases more urgent where suffering needed instant relief induced an appeal for advances on the deposit of distant parties. Sometimes a merchant would beg the Company to accept money and retire paper due elsewhere, which the mails could not reach in season. To all these, as far as possible, but thus far to a very limited extent, the Telegraph Companies have endeavored to make the Telegraph available. The opportunity for fraud has been the chief obstacle in the way of meeting these constantly recurring emergencies.

We need not say that demands of the character indicated have increased, both in number and urgency. They have come to make a provision for their relief imperative. This had often previously been attempted by outside parties, but without satisfaction. The Telegraph Company alone could do it safely to itself and promptly to applicants. It could also do the work more economically, and with a complete knowledge of the circumstances. Yet a score of years have elapsed before Companies have felt convinced of the practicability of establishing a system of money transfers which would relieve a wide spread public want as this has proved itself to be with entire safety.

Having now become satisfied, after careful deliberation, of their duty in the matter, the Western Union Telegraph Company have organized a "Money Order Transfer Department," under which it is arranged that at almost any city or town of any prominence in the United States, an amount not exceeding *one hundred* dollars can be deposited for instant payment to parties elsewhere. About five hundred of these points have been designated, and numerous applications are already being made for transfers of small sums, to meet all conceivable cases, many of them relieving actual distress. At fifteen large cities, the limit of transfer is increased to $6,000, to meet the occasional exigencies of business men. Thus a deposit of $6,000 can be made in San Francisco, and a note in Boston relieved the same morning.

The chief difficulty in the way of the inauguration of the Transfer system has been the apparent danger of the trust. Allowing the utmost for the integrity of all parties, the peril of the trust must be evident. We believe, however, that this difficulty has been successfully met, and that the following arrangements have made the Money Transfer system possible and satisfactory.

1. Every order to pay out money has to be done through the District Superintendent or Agent of a District, of which there are about twenty in all. Offices acting thus under the eye of an executive officer of the Company, are protected from fraudulent orders. When the notice of a deposit is given in the appointed cypher to the Agent of a District, he gives personal directions in another cypher, for its payment where required. Fraud therefore seems possible only by connivance with the Agent of the District.

2. The cyphers used in this correspondence have been arranged with great simplicity and adaption. Thus, a page of 100 or more ordinary words arranged in columns is first given. Against these, figures, corresponding to the number of words, but in disorder, are placed. Thus the twentieth word may have No. 1 at its side, and the first, No. 45. This is the detective or initial page, from which a word must be taken to commence a transfer message, and *in the order of the figures*, irrespective of the words. On the first message sent by a transfer office, therefore, the initial word would be that word against which was found placed the figure 1. On the second transfer the message initial word would be that against figure 2. Thus with the figures variously arranged, and with the initial always changing for each office, and the duplicate only in the hands of the Superintendent, the protection is evident and easy.

3. A second page of the same class of words as on the first page, denote the amount deposited. These are not subject to change. It is evidently important that no confusion be allowed in stating amounts.

4. As an additional precaution, the "initial" or "detective" cypher is ordered to be used by some offices as the first, others as the second, others the third, and others still the last word in the message. Inasmuch, therefore, as the same class of words are used for the "initial" and the "amount," it is virtually impossible for one, not in possession of the cypher, to tell which is the one or which is the other.

Here then the American Telegraphs enter a new and important sphere. It seems the initial of an era when a wide spread system of exchanges by telegraph may prevail. It is a field which invites study, and challenges the most sleepless discretion. Both of these we are persuaded will be given. At present, the transfer money service is forced upon the Company by a decent regard to public wants, and has already given much satisfaction.

We had a practical experience of the value of this system, which we give without charge. A gentleman of a somewhat chronic neediness, resident 500 miles further west, came to us one morning as we sat down to our appointed duties. We saw money in his eye, and prepared to say "No" as bravely as we could. So he commenced: "I am in a fix, (we knew it) and want to go home on to-night's train, (these fellows are always going home) but I have no money, but can get plenty as soon as I get home," Happily then we thought of the Money Transfer system. "My dear fellow," we exclaimed, as we smiled into his discomfitted eye, "You can have all the money you want, by sending a message to your mamma, directing her to deposit to your credit, and getting it at the front office." Our friend didn't see it, and left. We saved at least, ten dollars by his going.

It seems necessary to explain the terms and working of the Telegraphers' Insurance Association, as many desire to join and need explanation.

1. Applicants must be in the business, and of good health and habits. These three things must be endorsed by some superintendent or manager known to the executive. Forms will be sent when requested.

2. The fee on entering is $1.50 and a postage stamp for the return of the certificate. One dollar of this goes to the heirs of the first member who dies after an applicant is admitted, and the applicant so admitted is subject to an assessment of one dollar whenever that first death occurs, and one dollar at each subsequent death, each assessment being for the heirs of the next succeeding member who dies. The entire amount of an assessment goes to the heirs of the deceased.

3. Thirty days are allowed for the payment of an assessment. If any one dies and owes an assessment more than thirty days, the insurance is forfeited.

4. Members who have forfeited their membership can be restored by an application, blanks for which will be furnished, and by the payment of back dues.

5. Members are expected to keep the Secretary informed of their address, and notices of assessment are sent by mail to each person.

6. As an aid to members in keeping informed with respect to assessments and the association generally, the JOURNAL OF THE TELEGRAPH will be supplied to actual members at fifty cents per annum.

We give on another page a list of defaulters which seems discouraging, yet is what might have been expected. We believe the membership will hereafter acquire greater coherence and solidity. Some excellent men have allowed their names to drop out of the brotherhood by inattention. We regret this. We believe the organization has amply defended itself by its work and that it is destined for great good. Were it not so, we would decline the constant toil it brings us, and for which we ask only the knowledge of the benefit it confers. The addition of seventy-five members during the first three weeks of January, gives token of a better future and a largely widened sphere of usefulness.

THE POSTAL TELEGRAPH BILL.

The following is an abstract of the bill to connect the Telegraph with the postal service, recommended by the Senate Committee on Post-Offices:

SECTION 1 establishes postal telegraph offices at all Post-Offices on all telegraph lines, and at all other Post-Offices where the gross receipts for postage are $500 a year, if within ten miles of the telegraph lines. SEC. 2 fixes the rates uniform for equal distances, 25 cents between offices not over 250 miles apart; 50 cents between offices over 250 miles apart, and under 500; 25 cents for each additional 500 miles. Night rates, 25 cents for 1,000 miles. Rates to be refunded for delays or mistakes in transmission. SEC 3 provides for prepayment by stamps, and for the destruction of all telegrams within one month. SEC 4 fixes press rates for each one hundred words of special dispatches at 50 cents by night, 75 cents by day. It also fixes rates for press associations, and for private wires for newspapers. SEC. 6 defines the duties of the Fourth Assistant Postmaster General over the telegraph lines. SEC. 7 authorizes the Postmaster-General to contract for the transmission of telegrams at above rates, with parties who will furnish and operate the necessary lines of telegraph. SEC. 8 contains provisions against tampering with telegrams, and makes telegrams privileged communications as private letters. SEC. 9 authorizes the Postmaster-General to reduce the rates in the manner therein prescribed. SEC. 10 incorporates the Postal Telegraph Company for the performance of the postal telegraph service on behalf of the Postmaster-General. SECS. 11 and 12 authorize the Company to buy existing lines, and obliges it to purchase all such lines, if required by the owners thereof, at an appointed value. It fixes the capital stock at an amount not exceeding the last cost of its lines. SEC. 13 authorizes the Company to open offices wherever the wants of business may require. SEC. 14 authorizes Congress to purchase the lines at any time, at an appraised value. SEC. 15 reserves to Congress the right to alter or amend the act.

The proposal as will be seen above, is to establish a Telegraph Company which shall

1. Be a monopoly pure and perfect.

2. By agreeing to certain rates of charge, the business of the entire Continent shall be assigned to it without recourse for damages, the evidences of transmission to be obliterated by the destruction of all original messages within thirty days.

3. Confers the right on all existing lines to demand purchase by the Company so organized at specified rates, or rather, perhaps, compels all other lines to sell out.

4. Authorizes Congress to purchase the whole Telegraph property of the country at any time.

We shall watch the discussion of this report when brought up in the Senate for action, with interest. It seems like a scheme to secure a government telegraph control under the name of a private corporation, clothed with extraordinary powers and protection. To the public it ostensibly gives cheapness without responsibility; by the destruction of correspondence it obliterates the evidence of contracts; and renders impossible the gathering, after thirty days, of the traces of crime.

POPE'S Modern Practice of the Telegraph should be in the hands of every operator. Mailed promptly on receipt of price two dollars.

A LITTLE five-year-old boy was being instructed in morals by his grandmother. The old lady told him that all such terms as "by golly," "by jingo," "by thunder," etc., were only little better than other profanities. In fact, she said, he could tell a profane oath by the prefix "by." All such were oaths. "Well then, grandmother," said the little hopeful, "is 'by telegraph,' which I see in the newspapers, swearing?" "No," said the old lady, "that's only lying.'

THE BRITISH TELEGRAPH ADMINISTRATION.

HOW THE THING WORKS.

The telegraph operators who "struck" for higher wages lately have gone back to work, and submitted to the old system, and a snub besides. The cause of the strike may be gleaned from the following story, told by the *Cork Constitution*:—"A telegraph clerk was needed in the County Cork. A postmaster's daughter applied for the situation, and clearly evinced her superiority by thoroughly learning in a few days what often costs months of the closest application. She received a written appointment, fixing her stipend at six shillings per week, for which she was required to be constantly present in her office from morning until night. Under this arrangement she continued three months. But the other day the authorities resolved to give the economic screw a twist. So she received a communication to the effect that in future her salary would be reduced to £7 10s. per annum, or one penny per message. These terms she refused to accept, and so matters remained for some time. Three weeks' wages became due, and she was forwarded 7s. 2½d. as the remuneration for twenty-one days' unceasing occupation from morning till night, being 2s. 6½d. per week, or fourpence farthing per day." Fourpence farthing a day!

When Irish labor stood at starvation-point, some thirty years ago, the able-bodied farm servant received never less than sixpence per diem; and it will not be the fault of Mr. Lowe—for, perhaps, the "Second Secretary" is not originally to blame—if our Irish girls trained in the nice art of Telegraphy are not reduced to water-gruel and charity petticoats. The "economic fit" which has seized the Department would, probably, curtail even the breadth of those pauper skirts.

The other story is that—In a town, also in the County Cork, another postmaster's daughter was appointed to a post at 12s. per week. When the economic fit came on, she got notice that she would be reduced to 6s. per week. But she refused to work at the reduced rate, and a clerk was sent down from Cork to supply her place, drawing 30s. a week. This, of course, was only intended as a temporary measure, until a cheap operator could be procured. None such turned up, and at last it was found necessary to ask the postmaster's daughter to resume the position. She now saw her advantage, and, naturally resenting the glaring injustice, refused to comply with the request without an *increase* of salary. Finally, she was reinstated at 15s. per week! The *economy*, in this instance, produced its natural recoil; and we are convinced that, whether the strike hands in Dublin accept the Scudamore amnesty or not, the end of the matter will be a larger outlay on the Department, than if it had been managed from the start on fairer principles.

WE regret to have to record the death of Miss Kate Denny, Manager of the office of the Western Union Telegraph Co., at Easton, Pa., in that place on Monday, January 22d, after an illness of about four days. We sincerely mourn on the occasion of this death, for Miss Denny was a true and faithful woman, kind, exemplary and obliging, who never had to be called twice when on duty.

TRANSFER SERVICE.

New Money Order Office opened Feb. 1., at *Alpena, Mich.* E. P. WRIGHT, Transfer Agent.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
February 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since Jan. 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

368 Adrian, Ill.
357 Aledo, "
96 Amelia C. H., Virginia, re-opened.
368 Basco, Ill.
336 Brimfield, "
336 Bradford, "
251 Brady, Mich. Heretofore another line office.
356 Buena Vista, Iowa,
381 Brinckley, Arkansas, re-opened.
Cornelius, Or., tariff same as Portland, Or.
180 Clinton, O.
366 Clayton, Iowa.
336 Castleton, Ill.
130 Cash-Up, Pa.
368 Caluza, Ill.
377 Carman, "
266 Cave Spring, Ga.
368 Dallas, Ill.
317 Dayton, "
336 Duncan, "
368 Ferris, Ill. re-opened.
307 Fox, "
356 Guttenburg, Iowa.
* Gibralter, Mich.
317 Grand Ridge, Ill.
203 Huntington, W. Va.
[NOTE.—Huntington is at present an Other Line Ofs., but will be a W. U. and check direct Ofs. on and after Feb. 10.]
317 Indian Creek, Ill.
347 Ipava, Ill.
357 Joy, "
112 Kittanning Point, Blair Co., Pa.
326 La Moille, Ill.
368 Lomax, "
368 Loraine, "
151 Mingo Junction, Ohio.
468 Muskogee, Indian Ter.
494 Manor, Texas.
357 New Boston, Ill.
357 New Windsor, "
357 Nekoma "
* Ninety Six, S. C.
211 New Boston, Mich.
326 Ohio, Ill.
368 Oakland Ill.
367 Oxford Junction, Jones Co., Iowa.
114 Pamplin's, Va. re-opened.
346 Prophetstown, Ill.
Red River, New Mexico, tariff same as Trinidad, Col.
368 Rushville, Ill.
447 Rankin, Mo.
326 Sheridan, Ill.
317 Serena, "
368 Stillwell, "
25 Spencer, Mass. Heretofore another line office.
336 Lombard, "
356 Specht's Ferry, Iowa.
356 Turkey River, "
346 Tampica, Ill.
368 Ursa, "
357 Viola, "
357 Woodhull, "
326 Williams, "
346 Walnut, "
368 West Point, "
307 Yorkville, Ill. Heretofore another line Office.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.		Leaves this Line.
Gibralter, Mich.,	30	2	Huron, Mich.
Ninety-Six, S. C.,	50	3	Columbia, S. C.

OFFICES CLOSED.

Beattie, Ks.; Gibson, Ind. Terr.; Green Top, Mo., and Hepler, Kansas.

GENERAL INFORMATION.

The following is a list of offices on the Chesapeake and Ohio Telegraph Line, with tariff from Huntington, W. Va. (see Note after Huntington, given above), instead of Catlettsburg, Ky., as heretofore, and Greenbriar, White Sulphur Springs, Va. Business to be sent and checked via the cheaper route.

Barboursville, W. Va.	35	3	Huntington, W. Va.
	85	6	Greenbriar, W. S. Spgs., Va.
Big Bend Tunnell, W. Va.	30	5	Huntington, W. Va.
	40	3	Greenbriar, W. S. Spgs., Va.
Charleston, Kanawha Co."	45	4	Huntington, W. Va.
	75	5	Greenbriar, W. S. Spgs., Va.
Millers Ferry, W. Va.	60	4	Huntington, W. Va.
	60	4	Greenbriar, W. S. Spgs., Va.
Richmond Falls, W. Va.	75	5	Huntington, W. Va.
	45	4	Greenbriar, W. S. Spgs., Va.
St. Albans, W. Va.	40	3	Huntington, W. Va.
	80	5	Greenbriar, W. S. Spgs., Va.
Stretchers Neck, W. Va.	70	5	Huntington, W. Va.
	50	4	Greenbriar, W. S. Spgs., Va.

The name of the office heretofore known as Newport, Luzerne Co., Pa., has been changed to Wanamie, Pa., and business should be checked to Wilkesbarre, Pa.

Hereafter business for Marion and Hudson City, N. J., will be checked to Jersey City, N. J., at the Jersey City rate.

Business for Topton, Pa., will hereafter be checked direct, instead of to Lyons, Pa., as heretofore.

The P. O. address of Lake, Ind., is Lake Station, Lake Co., Ind.

378 Bowling Green, Ky., new office, given in last JOURNAL, should read 378 Bowling Green, Mo.

The office at 140 Kittanning, Pa., is in Armstrong Co.

Richmond Falls, W. Va., is also known as New Richmond, W. Va.

OFFICES HAVING "SPECIAL SHEET A"

Will hereafter check Spencer, Mass., same as "special rate" to Worcester, Mass., and Hoboken, N. J., same as "special rate" to Jersey City, N. J.

ATLANTIC CABLE BUSINESS.

We are notified that hereafter the "*Station from*" must in all cases be inserted, and *paid for*, in messages beyond Great Britain and Ireland.

WILLIAM ORTON, President.

EXPLANATION.

1. A number without an accompanying sign indicates that the holder of that certificate owes only assessment No. 24.

2. * Indicates that the holder has resigned, has been dropped for default, or is dead.

3. † Indicates that the holder owes assessments 23 and 24.

4. ‡ Indicates that the holder owes assessments 22, 23 and 24.

5. ‖ Indicates that the holder owes 21, 22, 23 and 24.

6. All certificates not recorded above are understood to be paid up.

The whole number of certificates issued to date is 1375.

THE Telegraph Construction and Maintenance Company have signed a contract with the Messrs. Bischoffsheim for the laying of an Atlantic telegraph cable from Great Britain to New York direct.

THE JAPS AND THE TELEGRAPH.

The members of the Japanese Embassy visited the Western Union Telegraph Office in San Francisco, at 4 p. m. January 23d, and were enabled to communicate direct with the Secretary of State at Washington, with Professor Morse, President Orton and others, and with the sons of the chief Ambassador, Prince Iwakura, now attending school at New Brunswick, N. J. The wires were connected through, and the following despatches were interchanged:

FROM THE SECRETARY OF STATE.

WASHINGTON, Jan. 23, 1872.

The Secretary of State congratulates the Japanese Minister on his arrival, and tenders a cordial welcome to the United States to himself and Embassy.

REPLY OF PRINCE IWAKURA.

SAN FRANCISCO, Jan 23, 1872.

Hon. HAMILTON FISH, Secretary of State:

Many thanks for your kind welcome to the United States. We shall leave here next week for Washington, when we shall have the honor of meeting personally and presenting our credentials as Ambassadors Extraordinary from His Majesty the Tenno of Japan to the treaty Powers.

Very respectfully,

IWAKURA, Ambassador Extraordinary.

THE PRESIDENT'S GREETING.

WASHINGTON, Jan. 23, 1872.

Prince IWAKURA, Ambassador Extraordinary, San Francisco:

The President will be much pleased to receive yourself and the Embassy, and hopes that your journey across the Continent may be agreeable and safe. You will meet in the American people and government friends looking with warm interest to all that relates to your country, and to the future relations between the Tenno government and the United States. The advent of such an embassy marks an epoch in the history of both nations.

HAMILTON FISH, Secretary of State.

FROM PROFESSOR MORSE.

NEW YORK, Jan. 23, 1872.

Professor Morse presents his best respects to the Japanese Ambassador, and welcomes him to the sphere of telegraphic intercourse.

THE REPLY.

SAN FRANCISCO, Jan. 23, 1872.

Professor MORSE:

The Embassy from Japan desire to inform Professor Morse, the inventor of the electric telegraph, that his fame is well known in Japan, and that within a few months one thousand miles of telegraph wire will be opened for business in their country.

IWAKURA, Ambassador Extraordinary.

FROM MR. ORTON.

NEW YORK, Jan. 23, 1872.

IWAKURA, Ambassador Extraordinary, San Francisco:

The President of the Western Union Telegraph Company presents his respectful compliments to the Ambassador Extraordinary of Japan, and tenders the use of the lines in the United States whenever His Excellency may desire them.

W. ORTON.

THE ANSWER.

SAN FRANCISCO, Jan. 23, 1872.

President WILLIAM ORTON and Vice-President MUMFORD:

Accept the sincere thanks of myself and associate Ambassadors for your kindness in placing such wonderful telegraphic facilities at our disposal.

IWAKURA, Ambassador Extraordinary.

FROM MR. MUMFORD.

NEW YORK, Jan. 23, 1872.

IWAKURA, Ambassador Extraordinary, San Francisco:

We shall be pleased to see you at the end of the line, and to have you inspect our office in New York, from which we greet you.

GEORGE H. MUMFORD.

FROM THE SONS OF IWAKURA.

NEW BRUNSWICK, N. J., Jan. 23, 1872.

IWAKURA, San Francisco:

Affectionate Father: We rejoice to hear from you. We wait for you in Chicago when we receive your advice.

TATO, MINAMI, ASASSI.

IWAKURA TO HIS SONS.

To TATO, MINAMI, ASASSI, Brunswick:

My Sons: I rejoice to hear of your welfare, and of the kind treatment you have received in America. We shall probably leave here during the middle of next week for Washington direct. Will advise you when to start to meet me in Chicago.

Your affectionate father, IWAKURA.

The wires never worked more perfectly, and the telegraphic interview was brief and delightful.

WE chronicle the arrival at Rome of Mr. Cyrus W. Field, from New York, to whose energy and perseverence we owe the Trans-Atlantic Telegraph. Mr. Field is a director of, and represents the company which owns the cable, and he has come to Rome to attend the International Telegraph Congress. It is understood that among other subjects to be discussed at the meeting, the American representative will propose to the congress the necessity of making a treaty between the powers of the old and new worlds, to whose interest it will be to guarantee the integrity and security of the ocean cables in time of war. The importance of this feature will be well understood when we refer to the events of the recent Franco-German war. We refer to the time when, in consequenee of some accident, the two cables which united England with the United States were insensible to the electric current. Telegraphic communication was thus suspended between these two countries for a period of several months. By good luck the cable which connected America with France continued to work. The French government used it on a large scale to order arms and munitions of war from New York. The French government thus gained from ten to twelve days in sending its orders, which time would have been lost if they had been obliged to send by mail. Prussia had the power during the war to cut the end of the cable on French territory so as to sever all communication. She did not do so and is therefore entitled to the thanks of all civilized powers. It is uncertain whether any other power would have been so scrupulous. It is therefore necessary to provide against all future contingencies, and, in the interest of the whole world, to prevent the ruin of such a gigantic enterprise whose principle object is to aid and protect commerce and industry. In adhering to the projected suggestion of Mr. Field the European powers will but imitate the ancient Greeks who bound themselves by an oath to respect, during time of war, the aqueducts which furnished water to the inhabitants of the neighboring cities. We know that the United States have already given their sanction to Mr. Field's proposal. We will also state that if Mr. Field merits the gratitude of all, by his having connected the two worlds by an electric current, he has also a special claim to our remembrance by the indefatigable zeal with which he has at all times promoted our country's cause. Mr. Field's name appears among the list of our Presidents who took part in the famous Reunion held in New York at the beginning of the year to celebrate the "Unity of Italy." All honor to Mr. Field, and we wish him a long prosperity and the success of his philanthrophic ideas.—*From the Roma L'Opinione, Roma.*

BORN.

At Plaister Cove, Cape Breton Island, January 11, to S. E Barton, a son—good sounder—and sends with left hand.

MARRIED.

CLEMANS—NEER—Monday Evening, Jan. 1, 1872. by Rev. J. G. Black, Mr. L. T. Clemans, Manager Western Union Telegraph at Urbana, Ohio, and Miss Sarah C. Neer, of Concord township.

DODD—ARMSTRONG—At Leroy, Mo., January 14, Geo. A. Dodd Manager W. U. Tel. Office, to Miss Lillian Armstrong, both of Girard, Kansas.

HUGGINS—PHELPS—At Mansfield, Ohio, Dec. 26, by the Rev. S. McBurney, W. J. Huggins, Opr. W. U. Tel. Office, Mansfield, O., and Emily Ogella Phelps, of same city.

MIXER—CHAPMAN—At Rochelle, Ill., January 16, 1872, Mr. C. L. Mixer, Manager W. U. T. Office, Geneva Lake, Wis., and Miss M. H. Chapman, of Phœnix, N. Y.

SKINNER—BURGESS—At St. Barnabas Church, Omaha, Neb. Wednesday Eve., January 12, 1872, by the Rt. Rev. Bishop Clarkson, assisted by Rev. G. F. Betts, Mr. Charles K. Skinner, Agent of C. & N. W. Ry., and Manager of the W. U. Tel. Co., to Miss Abbie H. Burgess, daughter of Rev. R. Burgess, all of Woodbine, Iowa.

MONTREAL TELEGRAPH COMPANY.

The imposing edifice which has just been taken possession of as the Toronto offices of this Company is not more striking in the harmony of its proportions and the elegance of design perceptible in its exterior than in the ingenuity, convenience and good taste with which its internal appointments have been adjusted. Every want detected by a keen sagacity during an experience of twenty-five years has been met; every possible accessory to the despatch of the Company's expanded business seems to have been carefully supplied.

Entering the main door on the corner of Scott and Wellington Streets, you find a spacious and well lighted and finished Receiving Room divided by a carved walnut counter, behind which stand the Receiving clerks; against the wall in front of the counter is a desk affording ample accomodation to the public for writing telegrams. From this room messages are conveyed by pneumatic tubes to the Superintendent's room one story, or the operating room two stories above; this is done instantaneously. From the same room the messages are delivered to the carriers by a wicket which communicates with the adjoining lobby. A capacious safe connected with this room contains sets of pigeon holes sufficient to accommodate copies of the messages for a period of eight months, each days despatches been kept entirely separate. There is also an inner safe for the use of the cashier. One flight of stairs above is the private office of the Superintendent, Mr. H. P. Dwight, connected by speaking tubes with all the other offices. Adjoining this room is that of Mr. B. Toye, the Assistant Superintendent. A room 40 x 60 feet in the front of this story is occupied by the Mercantile Agency of Messrs. Dunn, Wiman & Co., an institution well known and esteemed by our wholesale merchants as a reliable source of information relating to trades and traders. The entrance to these rooms is by the side door opening off Wellington Street. The next story is intended exclusively for the operating department, and contains sufficient accommodation for seventy lines. The room is divided in order to provide a separate department for ladies, whom it is intended to employ as opportunities arise.

The wires converge at the cupola and are brought directly down to a neat walnut case enclosing the "switch" from which they are led, carefully insulated beneath the floor, to the different operating tables.

On the third story is the battery room which supplies the power of all the work that is carried on in the operators' room.

One hundred and fifty new offices were opened last year, the total number of offices on the Company's lines and its immediate connections being 895, viz., in Ontario, 430; Quebec, 215; United States, 130; New Brunswick, 66; and in Nova Scotia, 54. The total uumber of offices of the Company and its immediate connections in the Dominion is 765, scattered from the remote points in Gaspé, in Quebec, to the extreme western section of Ontario. The total length of the wire is about 15,000 miles. Extensions more considerable than any made heretofore, are projected for next season.

Like most of the enterprises with which Sir Hugh Allen is associated, the Montreal Company has been one continued success. His wise counsel and prudent oversight has ever been employed in furthering its interests and directing its operations.

The Snperintendent in this western field, Mr. H. P. Dwight, is the life and soul of the Company, and his characteristic energy has been largely infused into it.

AMERICAN FIRE ALARM AND POLICE TELEGRAPH.

GAMEWELL & CO., PROPRIETORS,

NO. 104 CENTRE STREET, NEW YORK.

J. W. STOVER,
General Agent and Superintendent.

L. B. FIRMAN, Chicago, Ill.,
General Agent for the West and North West.

J. R. DOWELL, Richmond, Va.,
Special Agent for Virginia and North Carolina.

J. A. BRENNER, Augusta, Ga.,
Special Agent for Georgia and South Carolina.

L. M. MONROE, New Canaan, Conn.,
Special Agent for New England.

This system of Fire Alarm and Police Telegraph, with a Central office, or upon the

AUTOMATIC PLAN,

is now in operation in the following cities, to which reference is made for evidence of its great SUPERIORITY, VALUE and UNIFORM reliability:

Albany, N. Y.,	New Orleans, La.,
Alleghany, Pa.,	New Haven, Conn.,
Boston, Mass.,	Newark, N. J.,
Buffalo, N. Y.,	Omaha, Neb.,
Baltimore, Md.,	Philadelphia, Pa.,
Chicago, Ill.,	Pittsburg, Pa.,
Cincinnati, Ohio,	Portland, Me.,
Columbus, Ohio,	Peoria, Ill.,
Cambridge, Mass.,	Providence, R. I.,
Charlestown, Mass.,	Quebec, L. C.,
Covington, Ky.,	Rochester, N. Y.,
Detroit, Mich.,	Richmond, Va.,
Dayton, Ohio,	ndianapolis, Ind.,
Elizabeth, N. J.,	t. Louis, Mo.,
Fall River, Mass.,	St. John, N. B.,
Fitchburg, Mass.,	Springfield, Mass.,
Hartford, Conn.,	San Francisco, Cal.,
Jersey City, N. J.,	Savannah, Ga.,
Louisville, Ky.,	Syracuse, N. Y.,
Lawrence, Mass.,	Troy, N. Y.,
Mobile, Ala.,	Toledo, Ohio,
Montreal, Canada,	Toronto, Canada,
Milwaukee, Wis.,	Washington, D. C.,
New York City,	Worcester, Mass.,
Lynn, Mass.,	New Bedford, Mass.,
Lowell, Mass.,	Bridgeport, Conn.

The distinctive features of these systems of

FIRE ALARM AND POLICE TELEGRAPHS,

ARE,

First—The AUTOMATIC SIGNAL BOXES, the simple electro-mechanism of which enables any one—even a child—to give an *instantaneous*, *general*, and *definite* alarm of fire.

Second—The AUTOMATIC REPEATER, through which the apparatus may be distributed in a combination of circuits, and the entire system successfully worked without the constant personal attention of either operators or watchmen.

Third—The ELECTRO-MECHANICAL BELL STRIKERS, adapted to produce the full tone of the largest church or tower bells.

Fourth—The ELECTRO-MECHANICAL GONG STRIKER, for hose and engine houses, by means of which the location of the fire is instantaneously communicated to the members of each fire company.

These features combined form the

ONLY PERFECT, COMPLETE, AND RELIABLE SYSTEM

OF

FIRE ALARM TELEGRAPH IN THE WORLD.

Messrs. GAMEWELL & CO. are the owners of the original *FARMER AND CHANNING PATENTS*, one of the most important of which has just been extended for seven years. During the past seventeen years they have spared no expense or effort to secure improvements, and the systems are now covered by

MORE THAN TWENTY PATENTS.

The introduction and operation of the

AUTOMATIC SYSTEM

involves so little expense, compared to the benefit which it confers, that even small communities can profitably adopt and maintain it.

The co-operation of TELEGRAPHERS in securing its introduction into their localities is cordially invited, and their efforts will be duly appreciated and compensated.

Any information desired in regard to the above system will be cheerfully and promptly furnished upon application at the office.

A pamphlet setting forth more fully its advantages and superiority, has been printed, and will be supplied to Municipal Authorities and others interested in Fire Alarm and Police Telegraphy upon application as above.

ATTENTION OPERATORS !

PATENTED.

We would call your attention to our

TELEGRAPH OPERATORS' BADGE PIN.

Having completed our arrangements to manufacture, by putting in new machinery, and with a full force of workmen, we are now ready to supply the GREAT DEMAND for these Badge Pins. They are made of 18k gold, and are perfect fac-simile of the present MORSE, or curved lever keys, and the new style WESTERN UNION straight lever and FANCY BASE KEYS. We are now making two different sizes, one to be three-quarters of an inch long, and the other one inch long. Also, a very small, neat, BADGE KEY PIN for LADY OPERATORS. These are the only badge pins ever got up exclusively for Operators.

We are, also, manufacturing a complete set of RAILROAD BADGE PINS, for CONDUCTORS, BAGGAGE-MASTERS, BRAKEMEN, STATION AGENTS, and others, consisting of Punches, Passenger Cars (Pullman's Palace Pattern), Switch Targets, Coupon Tickets, &c. These Badges are all made of the most approved patterns.

PRICE LIST.

Key Pin, oval base, one inch long	$6 00
Key Pin, oval base, ¾ inch long	5 00
Key Pin, fancy base, one inch long	7 00
Key Pin, fancy base, ¾ inch long	6 00
Key Pin, oval base, (for Lady Operators)	5 00
Key Pin, fancy base, (for Lady Operators)	6 00
Key Pin Charm (for Watch Chain)	$5 00 and 6 00

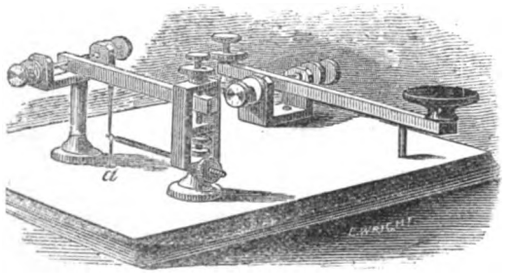
☞ The above are made with straight or curved Levers. ☜

Conductor Punch Pin	$4 00
Passenger Car Pin (Pullman's Palace Pattern)	6 00
Switch Target Pin	4 00
Coupon Ticket Pin (enamel)	4 00

☞ The above are all made 18k gold (warranted). ☜

Persons ordering Key Pins, be particular in giving style of lever and base wanted.

Any of the above will be forwarded by express, C. O. D., or by mail, registered, by sending amount and twenty-five cents extra to pay postage and registration fee.



Address,

HARVEY & DOW,

ST. JOHNSBURY, Vermont.

MECHANICAL TELEGRAPH INSTRUMENT

PATENTED MAY 31st, 1870.

For Students, Colleges, &c. No battery required. An ordinary key and sounder is placed upon a proper base. The sounder is moved by a lever under the base, connected with the key, making a perfect instrument for those wishing to learn the Art of Telegraphy. An expert could not tell, without examining it, that the instrument was not worked by a battery.

It should be introduced into every school and family where there are those who wish to learn the Art.

Hundreds of persons throughout the country desire to become expert Telegraphists, and are constantly seeking permission to practice in the various telegraph offices.

This instrument is an outgrowth of this pressing demand. The Inventor is himself a practical operator, now in active service. Operators and others wishing to teach or learn the Art, will be delighted with this instrument.

It can be placed anywhere, as it does not occupy a space more than six inches square.

Its cost is but $7, and there is no expense whatever to keep it constantly in working order.

We will send a copy of SMITH'S MANUAL, free of charge, with each instrument, to individuals or clubs. The instructions in this Manual are particularly adapted to those who wish to learn by sound.

Special and liberal terms to manufacturers.

Remittances can be made by certified draft on New York, Cleveland, or Pittsburgh, money by express, charges paid, post office order, or registered letter at our risk.

Parties ordering instruments, from points except well-known cities, will please give the name of county and State.

Price, $7. Silver Plated, Extra Finish, $10.

Address, D. W. PUTT & CO.,
Wellsville, O.

D. W. PUTT,
P. BRUNER,
W. G. BROWNSON.

These instruments can also be procured at the same price from L. G. Tillotson & Co., New York; Bliss, Tillotson & Co., Chicago, Ill.; Chas. Williams, Jr., Boston, Mass.; M. A. Buell, Cleveland, O.

WIRE IN BOND.

For the accommodation of the

SOUTH AMERICAN, CUBAN and MEXICAN TRADE,

we shall hereafter keep a stock of the Celebrated

"JOHNSON" WIRE,

both plain and Galvanized, in Bond, ready for shipment from New York.

PRICES AS FOLLOWS:

No. 9, Plain Annealed	4½ cts. Gold.
No. 9, Galvanized	5¼ "
No. 8, Plain Annealed	4¾ "
No. 8, Galvanized	5 "

This Brand of Wire is the best in the world, and has been adopted exclusively by the Western Union and many other Telegraph Companies.

We also continue to import this Wire for use in this country, notwithstanding the high rate of duty imposed by Congress in the interest of the monopolists. Any amount of it can be seen at our store at all times. The import duty on wire is now two cents per lb. gold, and 15 per cent. *ad valorem.*

OPINIONS.

NEW YORK, March 15, 1871.

Telegraph operators especially will find it almost indispensable after once having used it. All who have used it in this business speak very highly of it.

FRANK L. POPE,
Associate Editor of the "Telegrapher."

NEW YORK, April 21, 1871.

I fully accord in the above opinion of the Self-Supplying Pen-Holder, having tested it for some time.

SAMUEL F. B. MORSE.

VOL. V. NO. 6. NEW YORK, FEBRUARY 15, 1872. WHOLE NO. 103.

TELEGRAPH TRAIN ORDERS.

To the Editor of the Journal of the Telegraph:

I was much pleased to notice an article by "Observer" in regard to train orders being given to both offices at once. He claims the advantage of saving time in not occupying the wire so long as the old system. I do not think his plan any more modern than others, as I know of lines that have used that plan for fifteen years, and it was not new then. I consider it however the most safe and reliable of any in use—ignoring the time saving part which is the least among the many advantages it secures. I claim for it greater safety than can possibly be attained by any other mode in use, and am surprised to see the attempt made by "Green Flag" to throw contempt on that of which he appears to be ignorant. As "Observer" is probably a commercial operator and may not be aware of the many advantages of using this mode, I will endeavor to reply to the inquiries in the JOURNAL of February 1st:

1st. It is of great advantage to the despatcher and to the trains, from the fact that the order for each train will read alike, therefore there will be no error in regard to the time, station or train mentioned in the order.

2d. It is an advantage to the operator who has the operator at the other office for proof, in case there is dispute in regard to wording of the order. Do not understand me that these orders are not repeated. They are repeated, as all orders must be to insure safety. In case the train having the right has not arrived at the station to which the order is sent, the operator will be required to repeat the order and give the signatures soon as train arrives. Soon as the operator has repeated the order, O. K. can be given to the other train so it can proceed. Some one will say, "but suppose the operator fails to deliver the order to the train having the right." I would say to him, "we have the same assurance of delivery that we have when an order is sent to an operator to hold one train until another arrives." The responsibility rests on the operator in either case. Green Flag gives a sample of an order asking how it can be put into one order. It can be done very simply, but if G. F. is in the habit of using such orders as the one he gives, allow me to assure him it is one of the worst orders that can be used, and will prove an expensive one to any road using it. But to my sample: No. 1 A, No. 2 B. } No. 2 runs to A regardless of No. 1. Whenever it is possible to avoid it no train should receive orders at the station where it meets another train, especially a "regardless" order—which should never be used for a meeting order. A much better sample would be like this: No. 1 A, No. 2 C. } No. 2 runs to B to meet No. 1; or, No 1 and No. 2 meet at B; or, if you give a time order: No. 1 A, No. 2 C. } No. 2 has until 4.20 P. M. to make B to meet No. 1. I feel confident in stating that no order in which two trains are interested can be given in any better way, and will be as readily understood by train men. Any one desiring to know any other particulars in regard to it I will be glad to explain.—*Western Despatcher.*

RAILROAD ORDERS.

JACKSONVILLE, ILL., Feb. 6th, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—In No. 102 of the JOURNAL, I notice an article written by "Green Flag," in which he desires to know how the following orders, to wit: "To op'r A—Hold No. 1 for No. 2. (2.) To cond'r and Eng'r No. 2, B—Run to "A" regardless of No. 1," could be embraced in one order. I think the following order would be all-sufficient, namely:—To conductors and engineers Nos. 1 and 2—Trains Nos. 1 and 2 will meet at "A." This would be a positive order; one that would hold No. 1 at "A" until No. 2 arrived, and give No 2 the right to run to "A" regardless of No. 1. In regard to the idea advanced by "Another Observer," I would say that there need not be any difficulty in regard to right to the road, as where an order is given in this way, the operator should repeat the message, and get O. K. where it is not practicable to get the understanding of the conductor and engineer. This would make him responsible for the correct delivery of the order.

It is high time that something should be done to relieve the wires of a great amount of unnessary business; especially where one wire has to serve as railroad and commercial. I know of instances where very important commercial messages have been delayed from six to twelve hours, just on this account; and on reporting it to the railroad superintendent, his answer was, "can't be helped, railroad business *must* have preference." And in a *great many* cases the railroad business referred to might have served the purpose equally well if sent by train.

Yours fraternally, "A."

RAILROAD ORDERS.

MICHIGAN, February 9, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—Here comes Observer No. 3, in regard to train orders, and I suppose I am the best qualified man in the party to decide this matter, having never sent a train an order in my life. I will endeavor to relieve Green Flag of his study in the following order. To Conductor and Engineer, No. 1 A and No. 2 B, meet and pass each other at A. We presume there is not an operator on any road, that would not know enough to hold No. 1, without an order to that effect. These orders should be repeated and Dispatchers' acknowledgement given to conductor and engineer.

We do not agree with Observer No. 1, in regard to not repeating, as we are all liable to mistakes, but we do think the plan we mention, is the safest in all respects. That is, send the same order to all trains and offices interested at the same time. I have been an operator for years, and never yet heard an order in regard to meeting and passing trains that could not be sent to all trains at the same time.

Truly yours, OBSERVER No. 3.

FROM THE SAME.

To the Editor of the Journal of the Telegraph:

I wish to say a word in regard to the manner trains are reported on some roads, which is this. Example, "AS KB No. 12 AT 230 D 1232 KB," making twenty letters and figures to report one train at each office. Would it not be better to say, "No. 12 AT," making fourteen less letters and figures to each train, at each office. This is quite an item, where there are fourteen trains and fifteen offices, to report them in one day. If a train is off of time, it is well enough to mention the time. The manner we first speak of is practiced on our road for the purpose of keeping freight trains down to twelve miles per hour. Would it not be better to run freights twenty-five miles per hour, and take the salaries which are paid to the conductors, engineers, brakemen and firemen, who would not be needed in this case, and hire trackmen; string out the men with picks, shovels and spikes is our motto, and let the cars run.

Our conductors, engines, cars, and in fact everything connected with freight business could do double the amount of work, and with half the expense. This, we think, is one of the great mistakes in railroad management. They run twelve and sixteen-wheel coaches fifty miles per hour, and confine an eight-wheel box car to twelve. Hoping this may do some good and no harm, I remain as ever,

OBSERVER No. 3.

TELEGRAPH OFFICE,
OAKLAND STATION, KY., Feb. 7th, 1872.

To the Editor of the Journal of the Telegraph:

Although not a regular reader of your valuable paper, I managed to get a glimpse of it now and then. I noticed a communication in your last number in reference to the running of trains.

I have been *railroading* for about six (6) years, and I think I know a little about the running of trains. The running of trains, both on the same order, is one of the plainest of ways. By so doing, both parties know just what to do and what the other party have to do. So it is a great help in case of break-downs or accident. As "T. D." says: Suppose you get "O. K." to one, and through carelessness, &c., you do not get "O. K." to the other, it would not work. In running the old way, it is just the same if you cannot get "O. K." to the orders.

In answer to "Another Observer" question, how the following could be arranged so as to make one order. "No. 1 to operator A. Hold No. 1 for No. 2." "No. 2 conductor and engineer. No. 2 run to "A," regardless of No. 1." I should give the order in the following manner: "A" copy. "B" copy. To conductor and engineer No. 1, "A," and conductor and engineer No. 2, "B." No. 2 runs to "A," regardless of No. 1.

There both trains would know what to do, and it would answer all the same purpose as the order to "operator." The Western Division of the Pittsburg, Fort Wayne and Chicago run trains in that way, and it works admirably there.

Very respectfully, "H."

AN AMERICAN OPERATOR IN ENGLAND.

NEW YORK, January 27th, 1872.

To the Editor of the Journal of the Telegraph.

DEAR SIR,—I have received a letter from Mr. Thomas Carter, a gentleman well known to most American telegraphers, who left here last spring to visit his friends in England. He is now working in the Sheffield Telegraph Office. His letter contains some very interesting information relative to the English telegraphs under Government management, and believing that your readers desire all the reliable information on that subject that can be had, I now request you to allow me to lay before them, through your columns, some extracts from his letter. He writes under date of Sheffield, Yorkshire, Jan. 5th, 1872, as follows:

"Getting tired of doing nothing, I made application for a position as operator, through my friend the Manager of Sheffield office, and with the commendation I brought, and his influence combined, I was offered 25s. per week to commence with. (Unbounded generosity). I held out for 30s., but it was no go, and so, rather than do nothing all the winter, I accepted it, and began work last week. Of course, I felt rather clumsy at first, but after a day or two everything seemed to come natural again. There is no fast work needed here, and we are very easily worked, eight hours being a day's work all over the kingdom; overtime is paid for extra. I had to pass a medical examination, and make out and fill in a bushel basket full of papers—such a mess of red tape I never saw! The Government is certainly more liberal than the old companies were, and seem to be more careful of their clerks. In case of sickness we are supplied with a doctor free of charge, and no deductions are made from salaries for absence caused by illness. Each operator has a holiday of two weeks once a year, and all Sunday duty is paid for as overtime. I can make my salary average about 35s. per week, without hurting myself. This, of course, will seem small to you over there, but after all it will go as far as a good deal more in New York. * * * *

"You will be interested in hearing further about the telegraphers' strike; I was in Manchester at the time it occurred. It appears that ever since the transfer of the lines to the Government the operators have been promised, time after time, that a general revision of salaries should be made throughout the kingdom, and that the older clerks should be well looked after. This revision has been made in some places, but not in some of the larger cities, hence the dissatisfaction. An association was formed in Manchester, which spread to other towns where the same grievance existed.

"It flourished swimmingly for a time, but some member of the association disclosed the fact of its existence and its purposes to the officials, and they immediately discharged the leaders. This so incensed the operators that nothing but a strike would satisfy them, which they very foolishly did, they having no "circuit" in London, and having no chance of success as long as London remained loyal. It lasted only ten days, costing the Government thousands of pounds, and then the strikers began to weaken; all of them, with the exception of about thirty, are back at work; the remaining thirty can resume duty provided they will surrender the books and papers of the association, and this they refuse to do; they are being supported by subscriptions from all parts of the kingdom.

"The systems of working in use here are the Morse, the Wheatstone automatic, the Cooke and Wheatstone single needle, and the bell sounders. On the Morse circuits we use double currents on the "open circuit" plan; the key has about ⅛ of an inch play, and sending two or three messages with it tries one's arm. We use no sounders, all registers and paper; all the relays are of the "flower-pot" pattern. The Wheatstone automatic is the best and prettiest gotten-up instrument I have ever seen, and really does what they claim for it, 120 words a minute when pushed, but usually about eighty. I enclose specimens of the sending and receiving slips—that on the received slip was printed at the rate of 100 words per minute. The messages, previous to being sent, are punched on strips of paper, which the receiving operator runs through the sending apparatus, previously calling up the station or stations to whom it is addressed. The sender can regulate the speed of his instrument, and send fast or slow, according to the condition of the wire. On the needle and bell instruments the Morse code is used, a beat to the left representing a dot, one to the right representing a dash. The lines work splendidly, and they should do so, for they are so well built; crosses and grounds are unknown, unless something very serious happens to cause them.

"The climate is very depressing to me, after having been away so long—have had no winter here as yet—not seen a bit of snow. Small Pox is raging very badly nearly all over England; four cases in our office now.

"At this time of year things are very dull in England, and there's little or no excitement, the principal topics of conversation being the Tichborne case and the illness of the Prince. I spent a couple of days in London hearing the former. * * *

"Give my respects to all my old friends."

Here his letter ends, but he promises to write again soon, and communicate some more news. In case he does, I shall again trespass on your kindness to communicate it to your readers. C. S. H. S.

NEW PATENT MAGNETIC LOCK FOR SAFETY LAMPS.

On Wednesday, the monthly meeting of the Midland Institute of Engineers, which includes the whole of the mining engineers in Yorkshire and the greater part of Derbyshire, was held at the society's rooms, Barnsley, under the presidency of Mr. Hodgson, of West Yorkshire. There was a good attendance. A very able paper was read by Mr. Mills, of the firm of J. Mills & Sons of Newcastle-on-Tyne, on Craig & Bidder's Patent Magnetic Lock for Safety Lamps. In describing the Patent Magnetic Lock, which is in use at the Harecastle and Woodshults Colleries, Staffordshire, the writer showed that all previous inventions had hitherto failed in preventing the miners and other persons working in the colleries, from opening their lamps with forged keys and other implements. Referring to the numerous explosions which have occurred through the lamps being tampered with, the writer showed the great need for a lamp which could not be opened except by those in charge. He further explained that the lamps are self-locking, by being screwed round, and they cannot be opened except by the aid of a powerful magnet, which is kept in the possession of the lamp-keeper. The invention or principle can be applied to any kind of lamps in use, at a moderate cost; the invention not entailing more than about one shilling per lamp. The weight of the magnet used is about a quarter of a hundred weight; the cost with frame, being £4. 15s. 0d. The locking arrangement is very simple, and is inclosed within the lamp, which is more readily opened than those with the common lock. After some discussion, the paper was ordered to be printed by the society, together with the diagrams illustrating the locking of the lamps.

DESCRIPTION OF AN ELECTRIC TELEGRAPH.—A book with this title, which was first printed in 1823, has just been republished in London, by Sir Francis Ronalds. Before 1823, he sent intelligible messages through more than eight miles of wire, insulated and suspended in the air. If the experiments which he then made had been only suggestions, this would have been remarkable, but as the scheme was put into actual practice, it ought to connect his name with the history of the electric telegraph.

NOVEL DANGER SIGNALS.—Men are now engaged in erecting novel danger signals at every bridge and tunnel on the Hudson River Railroad, to warn brakemen, who are compelled at times to run along on the tops of trains, of their near approach to such dangerous places. A pole is erected by the side of the track, and an arm projects from it at the top, over the track. From this arm hangs a wire fringe, low enough to strike a brakeman on the front-piece of the cap or against the face, if he is standing up as the train passes. This perceptibly notifies him that he is only one hundred feet from the bridge or tunnel, and must lie down at once. The blow inflicted by the fringe is momentarily a stinging one, but produces no evil results.—*Syracuse Standard.*

ELECTRO-MAGNETIC WATCH-CLOCKS. — One of Hamblet's electro-magnetic watch-clocks has lately been placed in Bureau of Engraving and Printing at the Treasury Department at Washington; the Amoskeag Manufacturing Company at Manchester have a clock for ten watchmen; and the Manchester Printworks have one for eight watchmen. It is very interesting to watch the progress of the men, walking through the buildings, which can be easily done by observing the clock in the office. Clocks are now in process of construction for the Harmony Mills, at Cohoes, N. Y., for ten watchmen; the new offices of the Pennsylvania Central Railroad at Philadelphia, for three watchmen; and one for the House of Correction at South Boston, for four watchmen; besides many for single watchmen, at various places. These clocks are all to be set up under the personal direction of Mr. J. Hamblet, Jr., and are being made by E. Howard & Co., of Boston, Mass.

NEW USE FOR ELECTRICITY.—Electricity has achieved a new triumph. Already employed to restore vigor and nimbleness to the gouty limbs of decrepit *bons vivants*, the recent discoveries of Dr. Bernier, a French physician, show electricity to be an efficient remedy for the evil effects of excessive drinking on the human nose. The doctor maintains that, by the application of an electric current to noses even of the most Bacchanalian hue, the flesh may be made "to come again as the flesh of a little child;" and he supports his assertion by a case performed on a female patient of his own, a woman of high rank.

VANDERBILT wants to buy the Hoosac tunnel for a family vault. The Pennsylvania Railroad requires the Boston, Hartford and Erie road to supply Thomas Scott with wooden nutmegs and shoepeg oats for feeding his numerous State Legislatures. First-class in geography, stand up? What is the population of the United States? Answer: Five, viz., Thomas Scott, Cornelius Vanderbilt, Leland Stanford, Jay Gould, and William Orton.—*Chicago Tribune.*

THE SCHOOL FESTIVAL.—This beautiful little Quarterly Magazine, devoted to new and sparkling matter for *School Exhibitions* and public days, is received for January. No teacher or pupil should be without it. It costs only fifty cents a year; single copy, fifteen cents. Write for it, to ALFRED L. SEWELL, Publisher, Chicago, Ill. Send your subscriptions *now* and you will not regret it.

SCIENTIFIC AND PRACTICAL INFORMATION.

THE EFFECT OF LIGHT ON SMALL POX PUSTULES.

Among the many investigations now being made of the chemical action of light, there are none more interesting or more important than those which are directed to the observation of its effects on the health. It has been observed by Dr. Weber that the sensibility of the skin is very much increased in those parts of the body which are always exposed to the light, and this difference has even been measured by that eminent physician. This remarkable fact is especially observable on persons suffering from small pox, the severity of the skin disease being visibly augmented if the patient be not confined in a dark room. Dr. Waters has recently published a paper on this subject, in which he states that if the room be so darkened that not a single ray can enter it, the effect is to arrest the disease at the papular or vesicular stage; it never becomes purulent, and the skin between the vesicles is never inflamed or swollen; *liquor sanguinis* is not changed into pus, nearly all the pain and itching are absent, and the smell is, if not entirely removed, greatly diminished. Another advantage, important in a therapeutical point of view, is the assistance given to medicines, the absence of light increasing the excretory powers of the skin.

TARIFF BOOKS.

ELGIN STATION, Feb. 7th, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR;—The Western Union Telegraph Company would, I think, confer a favor to all managers, and benefit themselves if they would cause to be issued quarterly, or oftener, a complete revised and corrected Tariff Book (got up similar to the Supplement, dated May, 1871,) complete in itself; all the operators agree that the present book and mode of corrections is a downright nuisance.

This week "Bobtown" is in square 100, next week it is in another, now its name is changed. All space is filled, and "interline," "scratch," rub out, &c., all this could be saved; all operators would rather pay one or two dollars per year to save this vexation, and how much would the Company save. They could well afford to furnish such a work free, or at a very small price. If the suggestion is good it is free.

D. N. T.

CHILLICOTHE, O., Jan. 29th, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—Will you please notify telegraph managers and superintendents, of an unprincipled telegrapher, by name, T. J. McSweeny, who is going the rounds, practising impositions upon companies where he is unknown. He has recommendations from good parties, but of an old date. If he, at any time, merited confidence, he has forfeited it. He formerly read law at Wooster, O. His "modus operandi" is to work for a few days, get possession of money enough to compensate services and suddenly depart, leaving all bills unpaid. His sojourn with this Company was one night received; and fearfully *bulled* one commercial message, struck out next day. In the course of a few days he was employed by the Western Union Company, Little Miami Railway Company, Ohio and Mississippi Company, Pittsburg, Cincinnati and St. Louis Railway Company, and this Company. When last heard from, he was "on the wing."

Very respectfully, J. N. MILLER,
Manager of Telegraph.

We publish the above because a responsible name is attached to it, but with no knowledge of the circumstances except as given.

VARIOUS THINGS.

To the Editor of the Journal of the Telegraph:

In reply to "Observer," I would say that the first great requisite in train dispatching, is to insure absolute safety. If the usual wire is taken up to the disadvantage of other business, an additional wire should be strung. This is the course adopted by the Railroad Company, by whom I am employed. It seems to me that "Observer's" plan can not work to advantage if safety is required.

I have a suggestion to offer, which is, that no man should be allowed to occupy the position of "train dispatcher" until he is thoroughly acquainted with every mile of the division over which he is to have charge—with its stations, bridges, and side tracks. He should, at least once in six months, pass over his division. I see the force of this suggestion every day in my own experience.

I fully concur in your interpretation of the rules in regard to "Red" messages. The rules are not understood by many. I once received a half rate message at 8 P. M., from an office in Missouri, with an urgent request to "deliver quick, and send answer to-night, if possible!"

Your decision (JOURNAL, Feb. 1st.) as to postscripts after signature, is not only correct, but timely. These postscripts are getting to be a nuisance; while there is not only no rule for it, but no reason for such a rule.

What is the matter with the "Supply Department?" My requisition sent October 1st, 1871, was not answered; and I still wait response to requisition of January 1st, 1872. I am west of Chicago.

We need more instruction in regard to batteries. In the ordinary Daniell battery, (local) should the sulphate of copper be suspended near the surface in a pocket—so-called—or placed at bottom of jar? Some locals have a glass jar. Some locals have a glass jar—half gallon capacity—and small strip of copper; others have earthen jars, two gallons capacity, and strip of copper, six by nine inches, both Daniell's; which is best? and is the large copper necessary? Yours, truly, MANAGER.

ANSWER—The sulphate should be placed in the pocket. Its action from thence is more likely to be equalized as it dissolves. When placed at the bottom the action is apt to be confined to the lower parts, leaving the upper weak. We incline to think, that where the zinc is large and copper small, with plentiful liquid, the battery is most constant and economic. THOS. JONES.

MONMOUTH, ILL.

THE cable for the South Pacific, manufactured in 1870, has not been laid, waiting quietly for the completion of the West India cables.

KANSAS BULLS.

January 26, 1872.

To the Editor of the Journal of the Telegraph:

Mr. Wayne Parsons, formerly of our Utica, N. Y., office, now working on the Kansas R. R. wires, sends annexed samples of "bulls" recently made "Out West." The "bulls" are genuine; and one—the substitution of 100 for *well* after words "one hundred" as if 'twere figure-duplication—is unique.

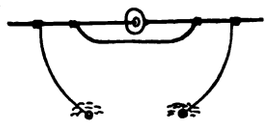
Respectfully, DOLAN, N. Y. Office.

1.	*Original.* "Meet her; send us one hundred: well"	7 paid.
	As received. "*Mother*; send us one hundred. (100).	7 paid.
2.	*Original.* "Mary's sick; come home quick."	
	As received. "Mary's *sock; cog log juice.*" *	

* Sending operator missread word.

A SCRAP OF HISTORY.

Interview in BERLIN, Feb., 1868, of Prof. MORSE with Baron Phillipsborn, Director General of Telegraphs.



"Professor Morse was in town last week. During his stay he called upon Colonel Von Chauvin, Superintendent of the Bund Telegraphic System, to make sundry inquiries. After answering his questions, Colonel Von C. said that the operators had heard of his presence and would be delighted to see him. Mr. Morse assented to the presentation, and was thereupon shown into the large operating room; at a word from Colonel Von C. the occupants rose up and stood *a la militaire*. 'You have the honor to see before you, gentlemen, the Father of the telegraph said the Superintendent. All bowed and bowed again, till, as a friend says, who relates the incident, the fond parent seemed quite embarrassed in the presence of so much of his children. Herr Von Phillipsborn did not wait for him to be shown in, but on receiving his card, came out of the ante-chamber to meet him; then taking both his hands in his own he asked whether he really had the honor of speaking to Mr. Morse, or, as he said, "Mr. Morzey." There was a conference in session on a new postal telegraph treaty with Belgium, and he therefore begged Mr. Morse to allow himself to be presented to the Belgian Minister, the Belgian Postmaster-General, &c., &c. The formal introduction was prefaced and supplemented by a speech from Director Von P., in which he thanked Mr. Morse, in the name of his government, of Prussia, and of all Germany, for his great services. All of the gentlemens hook hands with Mr. Morse in turn, each paying him some fresh compliment—the Belgian Minister speaking French. To the second speech of the Prussian Director Mr. Morse replied: 'For the flattering reception which you have given me, gentlemen, I am very grateful, and I thank you for the complimentary way in which you have been pleased to speak of my services. It is very gratifying to me to hear you say that the telegraph has been and is a means of promoting peace among men. Believe me, gentlemen, my remaining days shall be devoted to furthering this great object.' After a repetition of the handshaking, Her Von Phillipsborn led his guest into a small cosily furnished room, saying as they entered, 'I have so very often thought of you, Mr. Morse, but I never thought I should have the honor of receiving you here. We are all so much indebted to you—Prussia is so much indebted to you. Here you can see how invaluable the telegraph was in the war of 1866. Here,' placing the forefinger of his right hand on a large telegraph map—'here the Crown Prince came down through Silesia. This is the line of march,' indicating it with the other forefinger, 'of Prince Frederick Charles. From this station the Crown Prince telegraphed Prince Frederick Charles, always *over* Berlin, 'Where are you?' The answer reached him also over Berlin. The Austrians were here,' said he, placing the right thumb on the map between the two fingers. 'The next day Prince Frederick Charles comes here,' the left forefinger joined the thumb, 'and telegraphs the fact, always *over* Berlin, to the Crown Prince, who hurries forward here.' The forefinger of the right hand slipped under the thumb, as if to pinch something, and the director looked up. Perhaps he thought of the July afternoon when sitting listening at his little mahogany-tapped table, over which had passed so many important messages; he learned that the cousins had joined at Konigsgratz, a junction that decided the fate of Germany and made Prussia what she now is, a junction which without the telegraph, 'always *over* Berlin,' would have been impossible.

McL."

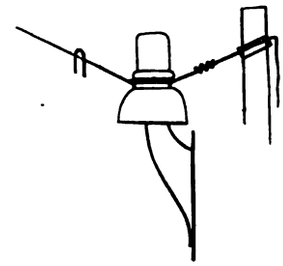
FAMILIAR TELEGRAPH TALKS.

Our last talk has brought us an enquiry, which being very simple, is easy of illustration and reply. It is related, however, to a large family of household troubles which it is about time were being remedied and got rid of. In the case presented, the wire of a certain railroad telegraph passed in front of a station, a glass knob inserted in the usual way, and wires led from either side to the station. The point of inserting these wires into the station was considerably lower than the main wire, and the wires were passed through the woodwork and united inside, the office having not yet been opened for business. Snow meantime fell and collected on each of the entering wires at the point of entry. Then came a partial thaw. Then appeared a heavy escape which was finally traced to the station described. We should have stated that the precaution had been taken to connect the main wire over the glass knob by a connecting wire. Query. Why should there be escape at such a point under such circumstances?



There is only one solution to this, and that is, that the melted snow must have traced its way down the wooden side of the station to the ground, thus leading off the current. The cut-off wire had no power to prevent this. Even had there been no snow, the damp air might have so entered the wood of the building as to have given an avenue of escape. We have stood sometimes inside of an office and received a shock from its damp walls where the main wire was suspended naked on nails and was then led to the operating table. Experience teaches that too much care cannot be exercised in providing against escape at the entrance to offices. Wires entered through the bare wood should never be allowed, unless the orifice be large and the wire made to pass through in the middle without contact to a rest inside, either on a level or sloping upward, and so protected that no snow can fill it. And yet this has been a most common fault, and, for all we know, may still be.

Let us resume where we left off in our last paper. We advised a cover to be made for the knob when wires were led to an office in that way. Here is a simple design for this. Any ingenious operator can make and apply it. Although apparently a small thing, it will pay to do it. It is a point in a young operator's favor when done.

Even with this precaution at the knob, a like care should be observed at the entrance. If the wires be copper which lead from the main wire to the window, see that the connection be thoroughly made and soldered. Insist on this. If you do not, rust will in time supervene and the chemical action which a little moisture will start between the copper and iron or zinced surface of the iron wire will soon corrode both, and your connection will deteriorate and perhaps be destroyed. Even where the connecting wire is iron the joint should be soldered, there being no pull upon it as in the main wire joints.

In reference to the entrance of the wire at an office, inasmuch as the wire usually inclines downward from the main line, it is necessary to have a bracket and insulator close to the point of entrance, and the wire from the insulator to the entrance sloping up. A simple and useful device is to bind a bit of wire on the main wire three or four inches from the insulator, so that the rain drops will fall before coming to the insulator. All these apparently minor devices

are useful, and an operator will be repaid by the care thus taken. We would slope the hole where entrance is made, inserting a piece of glass tube, so as to give every point a chance to be dry. And if the window is exposed, should a small roof be arranged to cover the brackets and the portion of the window where the wires enter, it will indicate that a wise and careful man is at work within. We believe that the bad working of many a line is caused by neglect of these little details.

Were we to express a preference for the point of connection with the office covered wires, it would be at the point between the insulator and the window, and that it also be most carefully soldered. The wires having been thus entered, many will think all danger to be gone, and that there is now nothing to do but hitch on and go ahead. It is far otherwise. There is exposure at every point. First, there is the combined switch and lightning arrester. The wires are to be carefully stripped of their covering and entered at the binding screws. See before doing so that the end is thoroughly brightened, and then see that the screw is pressed well home. Let it alone thereafter. The wood plate of the switch is supposably of hard wood and dry. If not, it will cause trouble. It must be kept free from dust, for dust takes up the dampness sometimes found in an office, and, being lodged round the ground wire connection, helps an escape. From the cut-out, one well-covered wire should be led unbroken to the back end of the key, the other to the relay, and for a way office, a third wire from the relay to the key. No joints should be allowed.

We ought to say here that we are very suspicious of pine operating tables, especially when thick. Sometimes the centre retains its natural sap, or retains absorbed moisture for a long time. Over and over again have we found messages being received on open keys where such tables were in use, the current passing through the moist centre of the table across from the fastening screws of the key. Once we covered a plain table at Pontotoc, Mississippi, with nice black glazed cloth, such as is used for table covers. We had to return two hundred miles to cut it out round the key. The current, much to our amazement, had established itself through the cloth, so subtle is it, and so carefully has it to be kept in its proper place. It is seeking constantly for short cuts. For this reason we prefer that the key base be screwed to the table, and the connecting rods with the binding ends be passed through without touching the table. This may be a refinement of care. Call it so, but you have a wide-awake thing to care for. No weasel was ever half so wide awake, and your care must be equal to it. We will endeavor in our next number to have a talk on the local battery respecting which so much has been said and written. We will be as thorough as possible.

CALLAUD BATTERY.

NEW YORK CITY.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—Will you please inform me in the next issue of your valuable paper, if you have space, how long it takes the Callaud Battery to be strong enough to operate a register, distinctly? And could not the process be shortened by using a solution of sulphate of zinc, instead of waiting for the zinc solution to become the proper strength, by generation? Yours very truly, OPERATOR.

Our battery keeper says: It takes forty-eight hours to be in condition for work, and which may be shortened by warmth. We believe it is better to wait for the natural attainment of strength than to secure it quicker by the use of sulphate of zinc.

OUR MAIN BATTERIES.

To the Editor of the Journal of the Telegraph:

I presume that nearly all concerned are aware of the following facts:

As a general practice, our main batteries (if any) are cleaned and filled with fresh material once a week, and the nitric acid changed once besides—the latter called "renewing." Observe:

On Monday morning we will suppose it is cleaned; it is then at its maximum strength. On Thursday morning the nitric acid is taken out, and fresh put in. On the following Monday morning, when the battery is at its weakest stage, a half, one-third, or a quarter is taken down to be cleaned, often leaving the wires to work on less than one-tenth the strength of current which they will have after the operation of cleaning and filling is completed.

Almost the same can be said of Thursday morning. Work on the wires is, in many instances, frequently quite or nearly suspended, especially if the "cleaning" or "renewing" happen in wet weather.

There is no time when a main battery can safely be much reduced; yet the current from the various main batteries (during business hours, too), often fluctuate from 100° (maximum) to 10° in strength. There is no economy in this; hundreds of relays are thrown out of adjustment by the change of a main battery or two—more or less confusion and delays always ensue. This state of things does not apply here especially. I have observed it for years, from the Atlantic to the Mississippi.

A remedy will cost nothing, so to speak. A better one than this may be found. I would suggest mine, hoping to call out a superior one. Thus: that a reserve of one-fourth the working number of cups be kept, placed and ready to fill, the battery stand to have the additional accommodation provided for the reserve in all cases. Now, a 60 cup battery would be kept this way: starting all clean and fresh liquids Monday morning; on Tuesday add the reserve 15, and take out 15; make ready the reserve, and on Wednesday fill and add the reserve, and take out the second 15; on Thursday take out the 3d, and on Friday the 4th 15. Now we have fairly started, and from this out there need be but little variation. The battery will be constantly ¼ new, ¼ one day old, ¼ two days old, ¼ three days old, or thereabouts.

Please comment on this. * * *

A CALIFORNIAN combats sleeplessness in a novel way. He recommends that the feet be drawn up so that the tips of fingers may touch the toes. This establishes an electric current, and sleep soon intervenes. In case the experiment should prove monotonous, we recommend that the fingers be made to drum on the toes. This opening and closing of circuit ought to produce a not disagreeable tickling sensation, in itself an aid to sleep.

RIGHTS OF OFFICES—RULE No. 20.

RALEIGH, N. C., January 30, 1871.

To the Editor of the Journal of the Telegraph:

There exists to some extent in this locality some difference of opinion relative to the discretionary power of operators, and as the organ of our Company, I would be pleased to have you settle this question through the columns of your valuable paper, and give us the true meaning of Book Rule No. 20. Suppose, for instance, a relay office, as this is, should receive a message destined for any point west of me in North Carolina, reading thus:

"To John Jones: Please send me scrap iron in car-load quantities; all over-charges will be paid." In sending this message to destination the check is challenged; matter is then referred by me (the relay office) to office where message originated. I receive in reply, "over-charges and car-load are counted as one word each." In face of such information direct from office where message originated, may I ask you to decide by what rule can the office at destination delegate to himself the right to stubbornly refuse to receive the message from me (a relay office) on account of not having a check made according to his own idea and opinion.

Please give this space in your next issue, accompanied by your reply and settle this vexed question.

ONE IN SEARCH OF RIGHT.

The Company's rule on this subject is one of the clearest of them all. The originating office has absolute authority in deciding the check and counting of words. No office has a right to detain any message on account of any mistake made in interpreting what constitute words, certainly not when informed that they were so interpreted. The stubbornness is specially objectionable, although an excellent quality when in the right.

WE neglected in our last to draw attention to the advertisement of M. A. Buell, Cleveland, O., one of the conscientious and painstaking manufacturers of telegraphic machinery, of which we have now so many. Mr. Buell makes to order all kinds of batteries, magnets, insulated wire, helicas, galvanometers, electric alarm apparatus and hotel annunciators, is reasonable in his charges, and thorough in his work.

The following is one of many testimonials sent him.

MACKINAW, January 15, 1872.

MR. M. A. BUELL, *Cleveland.*

DEAR SIR:—"The little monitor" came to hand this P.M Am well pleased with it. Think it is quite an ingenious piece of mechanism. The magnets are very strong; my battery (local) was weak when I put it in this afternoon, but it makes as strong a stroke as the old sounder with twice as much strength of local. This is a good point. Think an extensive sale awaits it. W. L. ATON.

THE Paris *Figaro* gives the following method of obtaining light instantaneously, without the use of matches and without danger of setting things on fire: Take an oblong vial of the whitest and clearest glass, put in it a piece of phosphorous about the size of a pea, upon which pour some olive oil, heated to the boiling point, filling the vial about one-third full, and then seal the vial hermetically. To use it remove the cork and allow the air to enter the vial, and then recork it. The whole empty space in the bottle will then become luminous, and the light obtained will be equal to that of a lamp. As soon as the light grows weak its power can be increased by opening the vial and allowing a fresh supply of air to enter. In winter it is sometimes necessary to heat the vial between the hands to increase the fluidity of the oil. Thus prepared the vial may be used for six months. This contrivance is now used by the watchmen of Paris in all magazines where explosive or inflammable materials are stored.

TESTIMONIAL TO SUPERINTENDENT F. H. LAMB.

VICTORIA, British Columbia, Dec. 21, 1871.

DEAR SIR:—The following letters will explain themselves:

MATSQUI, BRITISH COLUMBIA,
Telegraph Station, Dec. 1st, 1871.

To. F. H. Lamb, Esq., Dtstrict Supt. W. U. Tel. Co., and Ex. Supt. B. C. Telegraph Line.

SIR:—We, the undersigned operators of the British Columbia Telegraph Line, beg to express our sincere regret at your resignation of the Superintendency of This Line, and to offer this cane as a token of esteem, which please accept with our best wishes for your future happiness and prosperity. Signed,

Sarah A. Maclure, Geo. B. Murray, C. M. Chambers, John McCutcheon, J. G. Wirth, John Nicholles, T. R. Buie, John Murray, J. H. Carmichael, M. Ross, Henry Yeates, Alex. Lindsay, Jas. R. Leighton.

TO WHICH MR. LAMB RESPONDED AS FOLLOWS:

VICTORIA, Dec. 20th, 1871.

Dear Friends:

I was most agreeably surprised when Miss Maclure presented me in your names with your address and beautiful gift. I had not anticipated anything of this sort, and nothing was needed to keep in my mind a pleasant recollection of the operators of British Columbia. I thank you sincerely for this valuable cane, and assure that I shall always prize it highly as an expression of your good will and esteem, as well as a reminder of the pleasant associations with which I shall always connect it. With many thanks for your kind wishes for my welfare, believe me sincerely your friend, F. H. LAMB.

To Miss Sarah A. Maclure, Messrs. Murray, Ross, Chambers, Buie, McCutcheon, Leighton and others.

The cane is gold headed, rosewood, handsomely finished, with the inscription on the head, "To F. H. Lamb, Supt., presented as a token of esteem by the Operators of the B. C. Telegraph Line."

"VICTORIA."

THE Western Union Telegraph Company has been greatly favored in Johnstown by having in their employ a lady of the greatest accomplishments, both as a telegraphist and as a citizen, and, in return, they have manifested their gratitude in providing an office for her that cannot be excelled in neatness. Fourteen wires enter the office, and a switch-board register is put up, and desks, carpet, stove, railing, etc., etc., so that this estimable lady in charge has every comfort that heart could wish. We hope other lines will take the hint, and furnish their operators, at least, with reasonable comforts, and not work them fifteen hours per day. The Western Union line deserves the thanks of the people for their attention to their operators, and they may be glad that they have in their employ such an operator as Mrs. Ogle.

POST-OFFICE TELEGRAPHS.—Great efforts have been made to provide aid to the Postal Telegraph Department from the Royal Engineer Corps to help in meeting the difficulties caused by the strike of telegraph clerks. Yesterday a second detachment of men from the 4th Company at the School of Military Engineering at Chatham left head quarters for London, for service as telegraphists under the Post-master General. Other men are now being taught the use of the telegraphic instruments at the School, and when proficient they also will be sent to London. The party of Engineers who left Chatham for London on Friday, to act as telegraph clerks, after they had been joined by parties from Aldershot and Dover, were sent on to Dublin, to be employed in the Post Office there.

Amongst the new cables manufactured and laid during the year may be mentioned the cable in the Grecian Archipelago, in Grecian and Turkish waters, amounting altogether to 560 miles, connecting up the various isles, including Candia. These cables were manufactured and laid by the Telegraph Construction and Maintenance Company, who have the concession for the above places.

LIST OF GOVERNMENT DELEGATES AT THE INTERNATIONAL TELEGRAPHIC CONFERENCE, AT ROME, DECEMBER, 1871.

Austria and Hungary:—M. Brunner de Wattenwill, Aulic Counseller, Director General of Austrian Telegraphs. M. Edmond D'Ary, Counseller attached to the Ministry of Hungarian Commerce. M. Borowiczka, Secretar; to the Director General of Austrian Telegraphs.

Belgium:—M. Vinchent, Chief Engineer and Director of Telegraphs.

Denmark:—M. Martin Levy, State Counseller and Compartimental Director at the Ministry of Finances. M. Faber.

France:—M. Ailhaud, Inspector General of Telegraph Lines.

Germany:—Colonel Meydam, Director General attached to the German Telegraphs. M. Gumbart, Counseller at the General Direction of Communinations, and Director of the Bavarian Telegraphs. M. De Klein, Director of the Wurtemberg Telegraphs.

Great Britain:—M. Alan Chambre, representing the Post Office. Lieutenant Colonel Robinson and Major Bateman Champain, for the Government of India.

Greece:—M. Salachas, Secretary of the Greek Legation.

Holland:—M. Starin, attached to the Ministry of Finances, charged with the Direction of Telegraphs.

Italy:—M. E. d'Amico, Director General of Italian Telegraphs. The Chevalier E. Ponziovaglia, Chief of Division of Italian Telegraphs.

Japan:—M. Shioda, Secretary of the Japanese Legation.

Luxemberg:

Norway:—M. Nielsen, Director of Telegraphs.

Persia:—Major Bateman Champain, R. E.

Portugal:—M. Valentin Evaristo do Rego.

Russia:—M. le General de Luders, Private Counseller, and Director General of Telegraphs. M. Krapoukin, Court Counseller, Section Chief in the Telegraph Administration and Secretary of the Director of Russian Telegraphs.

Roumenia:—M. le General Prince Jean Ghika.

Servia:—M. Mladen Z. Radoycovitch, Secretary of the Direction of Posts and Telegraphs.

Spain:—His Excellency the Marquis de Mortemar, Envoy Extraordinary and Minister Plenipotentiary of H. M. the King of Spain to H. M. the King of Italy. M. Hippolyte Aranyo, Sub-Inspector of Telegraphs.

Sweeden:—M. P. Brandstrom, Director General of Telegraphs.

Switzerland:—M. Lendi, Director of Telegraphs. M. Louis Curchod.

Turkey:—M. Mehmed Izzet Effendi, Inspector General of Telegraphs. M. Yanco Effendi, Chief of Division to the Ministry of Posts and Telegraphs.

THE TELEGRAPH IN CHINA.

A scrap from the New York *Express*, while James Brooks, Esq., was in China.

"An event has just occurred which will hasten the erection of Telegraphs. The grand Pekin Council of Scholars have just awarded two competitive prizes to two Cantonese scholars, the highest honors of the empire. The news was sent from Shanghai by sea telegraph to Hong Kong, and reached Canton days before the news could come overland. The Cantonese were astounded, and discredited the intelligence until the long-looked-for Pekin *Official Gazette* came overland and confirmed it. Then there was wonder and marvel over that intelligence, and all China, from North to South, is asking if it will do to give foreigners the means of more rapid intercourse with the exterior of our empire than we ourselves have. Interest, their trade and commerce, I think, will soon dispose of that *Fung-Shuey*, and give China the Telegraph. 'The graves of our ancestors,' scattered over every little field in China, and will be more difficult and dangerous to be dealt with than this *Fung-Shuey*; but the 'graves of our ancestors' will have to go at last. All these opinions, even superstitious, in a *freeish* sort of country like this, have, however, to be respected, even by Emperors and mandarins. We have opened their great river, one of the greatest rivers in the world, and by steam we Americans do nearly all the coasting trade there, with Shanghai. Mandarins now prefer our boats to their junks to travel in. Europe and America have taught Chinamen how to cast cannon and to make rifles. Their factories, under our auspices, are almost equal to ours. Their rifle is as good as our Springfield rifle. Their ships of war are now putting on formidable fronts. If England again comes into conflict with China, it will not be so easy a conquest as in her two last Chinese wars."

WE have had the pleasure of a visit from Mr. A. M. Mackay the energetic superintendent of the lines of the New York, Newfoundland and London Telegraph Company. Mr. Mackay returned on the 29th to his home in St. Johns, Newfoundland. There is perhaps no territory in the world over which a telegraph is planted, so utterly wild and exposed. Yet there is none more uniformly in order, or whose business is transmitted with more regularity and despatch.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JAMES D. REID, Editor,
Executive Rooms, Western Union Tel. Co.,
145 Broadway, New York.

NEW YORK, FEBRUARY 15, 1872.

F. O. J. SMITH vs. PROF. MORSE.

There has recently appeared a communication from F. O. J. Smith, well known in the telegraph circles as the sharer of Prof. Morse in the fruits of his great invention, in which he, with characteristic malice, seeks to dim the laurels which the world, with common and warm consent have placed upon Prof. Morse's brow. It is a useless effort, especially when attempted by hands like his. It is worse than useless when the defaming paper is presented by one who has spent his strength in endeavoring to destroy what he could not rule, and in assailing and defaming those who served him best.

We deem it useless at this late day to enter any defence of Prof. Morse's claims to the honors which have been awarded him. The world, by a grand instinctive justice, aside from all the details of other men's merits, has made its selection and put the bays where they rightfully belong. Yet history will bear this record, that no man whom the general sentiment of society in all civilized nations have so marked as the subject of its honorable recognition, has more modestly accepted it, or been more outspoken in demanding that it be shared in the broadest manner by all who contributed to the grand end. Let all who have read the dedracting letter of Smith read the sublime speech of Morse at the Academy of Music. And let us perform one of our closing duties in placing on record a paper prepared for us by one of the acutest minds which ever held power in the Republic, now silent in the grave.

Prof. Morse's merits as an inventor have been severely criticized, and attempts have been made to confine them to very narrow limits. What they really are, is now pretty well established.

In 1819, Oersted discovered that a current of electricity, passing on a conductor, would deflect the magnetic needle when brought near it. This was the discovery of electro-magnetism.

In 1820, Schwieger conceived that if the current were made to pass many times around the needle by means of a coil of insulated wire, it would increase the force of the deflection. On trial the result was as he expected. This coil is called "Schwieger's Multiplier."

In 1825, Sturgeon conceived that if the electric current were sent through a wire coiled around a piece of iron, it would produce magnetism in the iron. He tried the experiment by insulating a round bar of iron, winding a naked wire spirally around it, and passing a current through the wire. The iron became magnetic. This was the invention of the electro-magnet.

About 1830, Prof. Henry conceived that if Schwieger's multiplier were applied to Sturgeon's electro-magnet, it would much increase its magnetic force. He wound insulated wire around the naked iron bar, making many turns, and, passing the current through it, found the result to be as he expected.

A variety of batteries had been invented.

One thing was yet wanting; that was, some means of renewing the magnetic force of the electric current before it becomes entirely exhausted by reason of the length of the circuit. That desideratum Prof. Morse supplied by his combined circuits. This, with his alphabet, and the new mechanism employed by him, constitutes Morse's invention; and these, in combination with the new result produced by him, are all he claims.

Truth is slowly making its way against error. Even the adversary counsel, in an argument before the Supreme Court of the United States, admitted that Prof. Morse was the first to invent "*a practically useful electro-magnetic marking telegraph.*" The world will not hesitate to believe that which interested counsel do not think it expedient to deny.

There is one main feature of his invention, however, which some men are still disposed to deny to him. It is the combined circuit. Their denial is based entirely on a misapprehension of some of Prof. Henry's statements, contained in sundry depositions. We deem it unnecessary to analyze those statements, because we have conclusive evidence, in a letter from Prof. Henry himself, that he knew nothing of that part of Morse's invention until more than two years after it was perfected. While Morse was in Europe in 1838-'39, Henry borrowed his wire of Dr. Gale, for the purpose of exp rimenting upon electro-magnetism at Princeton. On his return, Morse wrote to Henry, approving the loan of the wire, and, among other things, inquiring whether in his experiments he had become acquainted with any fact tending to show that his plan of an electro-magnetic telegraph was impracticable. To this Prof. Henry answered as follows, viz:

"PRINCETON, May 6, 1839.

DEAR SIR: Your favor of the 24th ult. came to Princeton during my absence, which will account for the long delay of my answer. I am pleased to learn that you fully sanction the loan which I obtained from Dr. Gale of your wire, and I shall be happy if any of the results are found to have a practical bearing on the electrical telegraph.

I am acquainted with no fact which would lead me to suppose that the project of the electric telegraph is impracticable. On the contrary, I believe that science is now ripe for the application, and that there are no difficulties in the way but such as ingenuity and enterprise may obviate. But what form of the apparatus, or what application of the power will prove best, can, I believe, be only determined by careful experiment. I can say, however, that, so far as I am acquainted with the minutiæ of your plan, I see no practical difficulty in the way of its application for comparatively short distance; but if the length of the wire between the stations be great, I think some other modification will be found necessary in order to develop a sufficient power at the further end of the line.

I shall, however, be happy to converse freely with you on these points when we meet. In the mean time, I remain, with much respect, Yours, &c.,

(Signed,) JOSEPH HENRY.

To Professor MORSE.

This letter establishes the following facts, viz.:

1. That Professor Henry had been experimenting upon electricity with Professor Morse's wire previously used by him in New York.

2. That, at the date of this letter, *upwards of eight years* after the publication of his experiments in *Silliman's Journal*, which have been largely quoted as virtually an invention of the electro magnetic telegraph, Prof. Henry had no definite idea of the form of such a telegraph, and supposed there were still difficulties which it would require "ingenuity and enterprise" to overcome.

3. That, although it has been confidently asserted that Prof. Henry's experiments, published in 1831, had shown how abundant magnetic force could be obtained on a circuit of any extent, Prof. Henry himself, *more than eight years thereafter*, deemed something more necessary for that purpose on circuits of great length.

4. That, supposing Prof. Morse's plan to be a telegraph of a single circuit, he deemed some modification of that plan necessary, when the circuit should be of great length, "in order to develope a sufficient power at the farther end of the line."

5. Prof. Henry did not then suggest, and the inference is irresistible that he had not before suggested, to Prof. Morse any specific modification calculated to effect that object.

Yet Prof. Morse, more than two years before, had not only devised, but actually constructed in his combined circuits, the "modification" Professor Henry, in May, 1839, thought still to be necessary, and in April, 1838, had embraced it in his specification then filed in the Patent Office.

Prof. Henry never claimed to have invented the telegraph or this part of it. He improved the electro-magnet, and thereby facilitated the invention. If his improvement were now used by an inventor in the construction of an electro-magnetic saw-mill, he would be just as much entitled to be considered the inventor of the saw-mill as he is now of the telegraph; and in that invention, Oersted, Schwieger, Sturgeon, and others would be entitled to an equal share.

We make this exposition, not to deprive Prof. Henry of a single laurel, but to put to rest the only remaining doubt as to the merits of Professor Morse as an inventor.

WITH the issue of March 1 we shall have completed five years of duty under the consolidated Western Union Telegraph Company, closing an entire telegraphic service of about twenty-seven years. It is with much feeling, and a big gulp of the heart, that we announce that, with that issue, our voice, as Editor of the JOURNAL OF THE TELEGRAPH, shall forever cease. A few words of farewell may appear in that number, and then we shall float away, as the dead float out on the currents of the deep dark rivers into the forgetfulness of the ocean. It is difficult thus to leave the family fire where we have been so happy. It comes very hard to shake hands which we may touch again on earth no more. But we shall lay down the pen glad in the consciousness of having done what we could, and in leaving the service in the esteem, we trust, of our associates in labor. We go to humor nature in her desire *for rest* to lengthen out, it may be, our lease of life by changing and limiting the nature of our engagements. We go with a profound conviction of the grandness of the service we leave behind us, and the multitude of generous men who remain to perform its duties. If our humble benediction on such be worth anything, it is most affectionately given.

THE Telegraph is a grave business, yet is not without its humorous side. For quiet genial mirthfulnes commend us to John Van Horn, the Southern General Superintendent. Here is his very latest utterance.

By some unaccountable telegraphing the following message was received at Washington, by the Railroad Superintendent, O. A. Stevens, who, for enlightenment, returned it to Supt. Van Horn, with the results following:

LYNCHBURG, Pa., Dec. 26, 1871.

O. A. Stevens, Gen. Supt. W. A. O. G. R. R. Co.:

General Superintendent Van Horn telegraphs that your list of Telegraph Franks for 1478 not to hand. If not forwarded, please send it soon. J. W. KATES, Supt.

MR. VAN HORN'S ENDORSEMENT.

Respectfully referred to Gen. T. T. Eckert, Gen'l Supt. W. Union Teleg. Co. I never asked for a list of Franks from this R. R. Co. in 1478. I was not in the Telegraph business at that time. I have traveled over the Georgetown road and know it is an old one; but I have grave doubts of its being in running order in the year mentioned. C. Columbus, an old friend of mine, came over this way fourteen years after the above date, but he never said anything to me about riding on that road. I think he went from Washington to Alexandria in a skiff. J. V. H.

WE return our sincere thanks to Mr. George Allen, Manager of the Western Union Telegraph Co's Office, Utica, N. Y., for a copy of Vail's pamphlet on the telegraph, from which we learned our first lesson in the mysterious art, and which to us at the time, was the most wondrous book of the century. Vast numbers of the pamphlet were sold at the time of its publication, and we poor pioneers had to depend somewhat for our daily bread on its sales, so we again thank Mr. Allen for the gift. It restores to us a friend of the good days when the people looked on a man who knew the telegraph as a minor Gabriel, not very minor either.

THE Western Union Telegraph Company have purchased the building on the south-west corner of Broadway and Dey street, and will proceed immediately to erect a building thereon suited to the growing necessities of the Company. It will probably take two years to complete such an edifice, but it will be worthy of the Company and the vast business which it is destined to do in the future, and for which the present premises, although spacious, are even now too limited for proper prosecution.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
February 15, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since February 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

426 Ashewa, Iowa.
210 Attica, Mich.
151 Bulger, Pa.
251 Climax, Mich.
410 Conway, Mo., re-opened.
200 Copac, Mich.
397 Comstock, Iowa.
210 Davison, Mich.
200 Emmet, Mich.
46 Florida, N. Y. Heretofore an Other Line Office.
210 Imlay City, Mich.
447 Hillsdale, Ks.
246 Kingston, Ga. Re-opened.
484 Keechie, Texas.
295 Letohatchie, Ala. Re-op'nd.
210 Lapeer, Mich.
154 Linwood, N. C.
83 Locke, N. Y. Re-opened.
336 Lafayette, Ill.
10 Lincoln, Me.
306 Milwaukee Stock Yards, Wis. Heretofore an Other Line office. Tariff same as Milwaukee, Wis.
406 Mason City, Iowa. Heretofore an Other Line office.
262 Milton, Ind. Re-opened.
307 Mich. Southern Crossing, Ill.
367 Onslow, Iowa.
321 Pocahontas, Tenn. Re-open'd
406 Plymouth, Cerro Gordo Co., Iowa. Heretofore an Other Line office.
* Palatka, Fla.
46 Pine Island, N. Y. Heretofore an Other Line office.
298 St. Ann, Ill.
47 Smithville, N. J.
337 Sherman, Ill.
8 Vanceboro, Me.
47 Whitings, N. J.
170 West Lafayette, O.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.	*Leaves this Line.*
Palatka, Fla.,	100 6	Lake City, Fla.

OFFICES CLOSED.

Athensville, Pa.; Cartersville, Ga.; Calhoun, Ga., Dalton, Ga.; Grays Ferry, Pa.; Jewett, Tex.; Kingsville, Ks.; Marietta, Ga.; New Memphis, Ill., and Ringgold, Ga.

Business for Grays Ferry, Pa., will hereafter be delivered from Philadelphia, Pa. Charges for delivery, 50 cents.

GENERAL INFORMATION.

Hereafter the "Tariff for Other Lines" from Chicago to the following offices will be as indicated below, instead of that published in Supplement to last JOURNAL:

The name of the office heretofore known as Midland, Wis., has been changed to Pardeeville, Wis.

Hereafter the "Tariff for Other Lines" to Pine Valley, N. Y., will be the same as to Havana, N. Y.

The office at 387 Oxford, Iowa, is in Johnson Co.

In list of new offices published in last JOURNAL, Manica, Ill., should read Monica; Tampica Ill., should read Tampico; and 336, Lombard, Mass., should read 336, Lombardville, Ill.

n list of N. W. Co.'s offices, in Supplement to last JOURNAL, Beloit, Wis., should have been omitted; it is a W. U. office, sq. 316.

"Half-rate" messages will hereafter be taken for, and received from, Tracey City and Sewanee, Tenn.

OFFICES HAVING "SPECIAL SHEET A"

Will hereafter check Jeffersonville, Ind., same as "special rate" to Louisville, Ky.

WILLIAM ORTON, President.

COMPLIMENTARY.

On the 15th instant a complimentary dinner will be given to our friend L. G. Tillotson, Esq., at the St. Nicholas Hotel, prior to his departure on the 17th for the Continent. We know none more worthy of such a compliment, or an occasion on which we would more gladly be present in response to an invitation with which we were honored, but which we are unable to accept. Mr. Tillotson has a life-long record of industry and liberality which have secured him both friends and fortune. We trust his trip to the old world may prove a delightful relaxation from the cares of business, and be fruitful of thoroughly restored vigor and health, and where we hope soon to follow him.

While abroad, Mr. Tillotson will proceed with his family as far as Italy, and will visit all the factories both in England and the Continent where wire or railway and telegraphic machinery are manufactured. He will thus unite business with pleasure, and will return in the close of the Summer ready for an enlarged provision of every article connected with the trade. May favoring gales "waft him o'er the deep," and if the Alabama question is still unsettled when he reaches these noisy "Britishers," we hope he will give them an excursion and settle the whole business in his own peculiar way. Good bye.

THE Cable to Porto Rico has been restored, and communication will soon be established with the W. I. Islands.

A good deal of excitement has ceen caused by the publication of the following letter:

"Anglo-American Telegraph Company (Limited).
"26 Old Broad Street, London, E. C., Jan. 10.

"SIR—The attention of the directors having been called to certain rumours affecting the condition of this company's cables, they consider it their duty to inform their shareholders that, according to the results of the tests reported by the company's superintendents at Valentia and Heart's Content, the insulation of the cables, both of 1865 and 1866, shows a considerable decrease. It is proper, however, to add that this decrease of insulation does not at present interfere with the regular and rapid transmission of messages. With a view of ascertaining more accurately the exact condition of the company's cables, the directors have determined to send Mr. Willoughby Smith to Valentia, to supplement the tests made by the company's superintendents. I am, sir, &c.

JOHN GRANT, Secretary.

Since the issue of this disturbing letter, we learn that Mr. Smith has made his examinations, and that the loss of insulation has been found to be solely in the shore ends; the deep sea cables remaining as perfect as before.

To the Editor of the Journal of the Telegraph:

Will you please explain, through the TELEGRAPH JOURNAL, the meaning of "Additional to Assessment, Nos. 23 and 24?" By doing so you will oblige me as well as other operators on this line.

Very respectfully,
G. A. CARPENTER, Operator.

It simply means remittances received since the first acknowledgements went to the printer's hands. It saves the printer much labor. The assessment is the same.

THE INFLUENCE OF THE JOURNAL.

To the Editor of the Journal of the Telegraph:

When the JOURNAL was first issued it occurred to me that it would become a power for good in the profession in proportion as it awakened a spirit of inquiry among those with whom it came in contact. For some time that awakening seemed a doubtful matter, but I am glad to acknowledge that all doubt has passed away, since every issue of the JOURNAL carries with it the proof that the minds of many operators are aroused to the importance of seeking a fuller understanding of the business in which they are engaged. So far the JOURNAL has been a success. I was anxious also about the editor. *Who* was he? *What* was he? Was he a man of broad views and generous feelings—capable of appreciating the efforts of the humblest employee as well as the efforts of those in power? Had he a hobby to ride, and, if so, what? Was his education and experience such that we could safely go to him for such information as could not be well obtained from other sources? Well, all this has been settled; and I believe there is no manager in all the broad land who does not feel like striking hands with the editor with thanks for the past and hope for the future.

So much by way of comment. To my brother operatives I would say, the JOURNAL will be a success in our individual case only in proportion as we are benefitted by it; and also that its success—in a great measure—depends on us. It is our duty, and shall be a privilege, to communicate to the JOURNAL any new facts which comes to our knowledge, in regard to the actual working of the lines, care of batteries, &c., &c., and equall your duty to enquire of the JOURNAL in regard to those points on which we are ignorant. When we earnestly begin to do this, then will the JOURNAL become a teacher, and its power and influence be mightily increased.

We need not be afraid to expose our ignorance in regard to the mysteries of our profession—those who can claim to understand it thoroughly, are few in number—and we shall never truly begin to learn until we admit our need of more light. From my own knowledge I can say that there is a wide spread ignorance among operators in regard to many things whish they ought to know, and this is not confined to the younger hands. I have seen operators of ten years' experience who had no idea *why* a reply was necessary.

MANAGER.

A KIND WORD.

ST. JOHNS, N. B.

DEAR SIR: * * I cannot allow this opportunity to pass without adding some expression of my appreciation of the sterling value of the paper so ably conducted by you. The high moral tone and generous spirit which have ever characterized your editorials are not the least of its virtues. Believe me, fraternally,

F. W. JONES.

BORN.

To Mr. Mat Davin, Operator, Boston, Mass., at St. Pierre' Miquelon, on Friday, 2d, a daughter.

To Thomas J. Calahan, Chief Operator, Brokers' Branch Western Union Telegraph Company, Boston, Mass., on January, 24th, at Woburn, Mass., a daughter.

DIED.

FREEMAN.—In the 24th year of her age, at De Lassus, Mo., at thirty minutes past nine o'clock, Friday morning, January 19th, after an illness of three weeks, Emma Rosalie, beloved wife of William T. Freeman, and daughter of the late Dr Bourgeat, of Point Coupee, La.

New Orleans papers please copy.

CHARLES A. KELLOGG.

On Saturday last, while in Rochester, N. Y., we were informed of the illness of Mr. Charles A. Kellogg, late of Memphis, Tenn., and the announcement that his death might be hourly expected. He was appointed as a messenger in the Rochester office soon after we became superintendent of the lines in that region, and remember him as an active, willing, obliging boy. Learning to operate, he soon became skillful at the key, and has served the Western Union Telegraph Co. since then, at several prominent points, and always, so far as we know, acceptably. His last position was in Memphis, Tenn., where began the breach in his constitution which has now terminated in death. He died on Saturday night, February 3, at 9 P. M.

One unpleasant circumstance occurred to us in this case, which we must mention. Young Kellogg learned of our presence in Rochester, during Saturday, and desired to see us, repeating and urging this wish with much frequency. On hearing of it, we arranged to go an hour or two afterwards, and started for that purpose. Calling on our way at the Telegraph office we were told that we had better not go, as consciousness was gone. Against our judgment but obedient to the message, we refrained from our visit until the next day. We found the door bearing the insignia of death. Within lay our friend, cold, and sheeted for the grave. He had called for us until 6 P. M. the night before, the exact time when the message was given us which prevented our visit. After that he sank away, and, at nine, died. We could only look at the hollow wasted form from which life and speech had fled. We missed the opportunity of comforting him in his last hours. We hope he had a higher and holier voice than ours to cheer him as he entered his last rest. His widowed mother will receive the hundred dollars promised by the Western Union Telegraph Company, in addition to the fund from the Telegrapher's Mutual Life Insurance Association, of which he had been a member since an early period. It will be a practical sympathy deeply appreciated and worthily bestowed.

LETTER OF SYMPATHY FROM THE OPERATORS.

To Mr. and Mrs. Kellogg:

AFFLICTED FRIENDS:—Permit us to assure you of our sincere sympathy in the great affliction which has fallen upon you and us, but doubly severe upon you who loved Charley as an affectionate son, whose gentle heart was ever that of a child's. We loved him as a friend and companion, in whom we could confide and trust. He was eminently faithful and companionable. In his profession he was an ingenious expert, and a valuable servant to his employers and the public. We mourn with you and deeply feel his loss, although we question our right to regret that he is gone. Charley is now free from suffering, and, we hope, in the full enjoyment of perfect rest and peace from all pain. We belive that God is good, and doeth all things well. Please accept our sympathy, and allow us to be your friends as we were his.

Yours ever truly,

(*Signed*)

ROCHESTER, N. Y., Office, Feb. 6, 1872.

Messrs. Reed, Gibson, Redman, Mulligan, Raquet and Agne acted as pall-bearers.

The funeral took place on Tuesday, February 26, and was largely attended.

RESPECTING THE BONUS.

February 8th, 1872.

ON THE LINE OF THE N. Y. C. AND H. R. R.,

J. D. READ ESQ., DEAR SIR:—Pres't Orton's letter of December 28, 1871 to you, says: "The Company will add to the payment made by the association, 100 dollars in each case of the death of a member of the association, who is *at the time in our employ.*"

This is well, but what will you do with several hundred of us who are denominated R. R. operators. We daily do all the business for the W. U. Teleg. Co. that is offered, but are *paid* and in the *direct* employ of the R. R. Co., and therefore, in case of our death, our heirs must be deprived of the benefits of this $100. Your humble subscriber is one of the *oldest* members of the association, and one of the *old guard*, who worked on the W. U. lines in the West, in the infancy of that company, when our eastern terminus was Buffalo. Many of our associations, best and truest men and women can be found on this and other railroads doing the business of the W. U. Teleg. Co. in connection with our other duties. I regret exceedingly being excluded in this manner, and I have no doubt many others feel as I do about this. It would not be a heavy tax on the Teleg. Co., should they include us, as we die hard. In fact should not be over anxious to die after the Company had spread its broad mantle of charity sufficiently to cover us all. We pay all assessments promptly and cheerfully, and feel that we are all brethren; and while laboring indirectly for the same great and generous company, pray that our cause may be considered and favorably passed upon, and in due time reported to us through the columns of the JOURNAL.

Very respectfully yours in haste,

HOLDER OF CERTIFICATE 735.

ANSWER.—We have authority for saying, that the hundred dollar blanket offered by Mr. Orton is wide enough to cover the holder of certificate No. 735, and all who, like him, labor in so direct connection with the Western Union Telegraph Co. It cannot properly cover members who serve other telegraph companies, who will no doubt make a similar provision to their operators when brought to their notice. No one should feel aggrieved because a company desires to benefit its own men by giving a hundred dollars to their widows at death, but should endeavor to have all companies act with like liberality.

HOW TO INCREASE THE MEMBERSHIP.

J. D. REID, *Esq:*

DEAR SIR:—Acting (by request of the members) as agent of T M. L. Association, I have caused the inclosed message to be sent to all telegraphers, with the hope that it may result in an increase of the membership. Would it not be well to state that I am prepared to furnish applications, &c., upon application. I have three applications to forward soon. Can a certificate be changed, as to the bestowal of the benefit money, for instance: suppose original made out to benefit a sister, and previous to death, a wife is taken; can the certificate be changed, by request of a member, from the sister to the wife?

Very respectfully,
D. C. HINSDALE, Supt's Clerk,
Sixth District C. D.

The heirs can be changed at any time, by written authority, and all who have neglected to name their heirs should do so without delay.

HOW TO DO IT.

INDIANAOPOLIS, Ind., Feb. 6, 1872.

All Telegraphers:

Your attention is called to the letter of President Orton, containing the resolutions of the Executive Committee of the W U. Telegraph Company, sustaining and offering aid to the Telegrapher's Mutual Life Insurance Association, in the JOURNAL of January first, 1872, also to articles found on pages 54 and 56, of the issue of February first. This Association numbers 1,375 members, seventy-five of which were added during the first three weeks of January. Acting for the Association in this district, I earnestly desire your hearty co-operation in making this Association a success, and hereby cordially invite you to become members of the Association, for which purpose, blank applications will be forwarded to you, upon application to the undersigned:—Supts of R. R. Telegraphs and Division Operators are requested to forward the above to every telegrapher on their lines.

Respectfully,
D. C. HINSDALE, Supt's Office.

A PROTEST.

NEW YORK, January 29, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—I desire to enter my protest against the proposed arrangement with the W. U. Telegraph Co., by which that Company shall become the custodian of the funds of the Telegrapher's Mutual Association and the virtual controller of its affairs, to the prejudice of members not in the employ of the former Company.

I would favor a small assessment for compensation to the officers of the Association, but can never sanction the transfer of its affairs to hands in which its usefulness is sure to become limited.

Respectfully,
W. H. MOAK, 433 Broadway.

REPLY.

We wish to assure every one that no one has the least control over the operators of the Association beyond its proper officers. We would as willingly deposit the money any where else on the same terms, if equally convenient and secure. The death bonus of one hundred dollars is a free gift and subordinates no one. We would be glad to see other companies do the like thing. The officers of the Western Union Co. have never intimated a desire or attempted in any way to limit the usefulness of the Association, or in any way discriminate in favor of its employees, except by providing this hundred dollars at death. Mr. Moak could scarcely ask them to extend this to those not in their employ. All funds are subject to the check of the Treasurer of the Association, and to his only.

16,000 MILES

OF

"JOHNSON'S" WIRE

USED BY THE

TELEGRAPHS OF THE UNITED STATES

DURING THE YEAR 1871.

This is sufficient refutation of all the intimations thrown out by the Manufacturers and Importers of other Wires, reflecting upon the acknowledged superiority of the Wire manufactured by

Messrs. RICHARD JOHNSON & NEPHEW,

MANCHESTER, ENGLAND.

Their Works are the Largest in the World.

The great advantage which they possess over other manufacturers is their patent process of drawing Wire in great lengths (averaging 1,200 feet).

All Telegraphers know that, in nine cases out of ten, breaks in Wire occur at joints, hence the less joints the fewer breaks.

Messrs. RICHARD JOHNSON & NEPHEW furnish three-fourths of all the Telegraph Wire used by the

ENGLISH GOVERNMENT.

This Wire is necessarily subject to the tests, etc., imposed by the English Post-office Department.

A large stock always on hand and for sale at the lowest market prices—both free and in bond.

AMERICAN FIRE ALARM

AND

POLICE TELEGRAPH.

GAMEWELL & CO., PROPRIETORS,

NO. 104 CENTRE STREET, NEW YORK.

J. W. STOVER,
General Agent and Superintendent.

L. B. FIRMAN, Chicago, Ill.,
General Agent for the West and North West.

J. R. DOWELL, Richmond, Va.,
Special Agent for Virginia and North Carolina.

J. A. BRENNER, Augusta, Ga.,
Special Agent for Georgia and South Carolina.

L. M. MONROE, New Canaan, Conn.,
Special Agent for New England.

This system of Fire Alarm and Police Telegraph, with a Central office, or upon the

AUTOMATIC PLAN,

is now in operation in the following cities, to which reference is made for evidence of its great SUPERIORITY, VALUE and UNIFORM reliability:

Albany, N. Y.,	New Orleans, La.,
Alleghany, Pa.,	New Haven, Conn.,
Boston, Mass.,	Newark, N. J.,
Buffalo, N. Y.,	Omaha, Neb.,
Baltimore, Md.,	Philadelphia, Pa.,
Chicago, Ill.,	Pittsburg, Pa.,
Cincinnati, Ohio,	Portland, Me.,
Columbus, Ohio,	Peoria, Ill.,
Cambridge, Mass.,	Providence, R. I.,
Charlestown, Mass.,	Quebec, L. C.,
Covington, Ky.,	Rochester, N. Y.,
Detroit, Mich.,	Richmond, Va.,
Dayton, Ohio,	ndianapolis, Ind.,
Elizabeth, N. J.,	t. Louis, Mo.,
Fall River, Mass.,	St. John, N. B.,
Fitchburg, Mass.,	Springfield, Mass.,
Hartford, Conn.,	San Francisco, Cal.,
Jersey City, N. J.,	Savannah, Ga.,
Louisville, Ky.,	Syracuse, N. Y.,
Lawrence, Mass.,	Troy, N. Y.,
Mobile, Ala.,	Toledo, Ohio,
Montreal, Canada,	Toronto, Canada,
Milwaukee, Wis.,	Washington, D. C.,
New York City,	Worcester, Mass.,
Lynn, Mass.,	New Bedford, Mass.,
Lowell, Mass.,	Bridgeport, Conn.

The distinctive features of these systems of

FIRE ALARM AND POLICE TELEGRAPHS,

ARE,

First—The AUTOMATIC SIGNAL BOXES, the simple electro-mechanism of which enables any one—even a child—to give an *instantaneous, general,* and *definite* alarm of fire.

Second—The AUTOMATIC REPEATER, through which the apparatus may be distributed in a combination of circuits, and the entire system successfully worked without the constant personal attention of either operators or watchmen.

Third—The ELECTRO-MECHANICAL BELL STRIKERS, adapted to produce the full tone of the largest church or tower bells.

Fourth—The ELECTRO-MECHANICAL GONG STRIKER, for hose and engine houses, by means of which the location of the fire is instantaneously communicated to the members of each fire company.

These features combined form the

ONLY PERFECT, COMPLETE, AND RELIABLE SYSTEM

OF

FIRE ALARM TELEGRAPH IN THE WORLD.

Messrs. GAMEWELL & CO. are the owners of the original *FARMER AND CHANNING PATENTS*, one of the most important of which has just been extended for seven years. During the past seventeen years they have spared no expense or effort to secure improvements, and the systems are now covered by

MORE THAN TWENTY PATENTS.

The introduction and operation of the

AUTOMATIC SYSTEM

involves so little expense, compared to the benefit which it confers, that even small communities can profitably adopt and maintain it.

The co-operation of TELEGRAPHERS in securing its introduction into their localities is cordially invited, and their efforts will be duly appreciated and compensated.

Any information desired in regard to the above system will be cheerfully and promptly furnished upon application at the office.

A pamphlet setting forth more fully its advantages and superiority, has been printed, and will be supplied to Municipal Authorities and others interested in Fire Alarm and Police Telegraphy upon application as above.

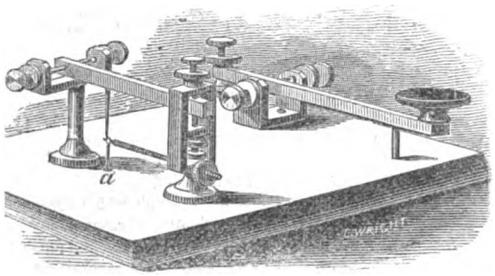
VICK'S FLORAL GUIDE FOR 1872.

THE First Edition of TWO HUNDRED THOUSAND copies just published. It is elegantly printed on fine tinted paper, in TWO COLORS, and illustrated with over THREE HUNDRED ENGRAVINGS of Flowers and Vegetables, and TWO COLORED PLATES. The most beautiful and instructive Catalogue and Floral Guide in the world—112 pages, giving thorough directions for the culture of Flowers and Vegetables, ornamenting grounds, making walks, &c.



A Christmas present for my customers, but forwarded to any one who apply by mail, for TEN CENTS, only one-quarter the cost.

Address, JAMES VICK,
Rochester, N. Y.

THE INDURTRIAL MONTHLY (FORMERLY KNOWN AS THE TECHNOLOGIST).—This instructive and useful journal, issued by the Industrial Publication Company, at 176 Broadway, N. Y., has just entered its third year, and is receiving a large share of popular favor. The articles are written with usual care, and many of them are beautifully and instructively illustrated. The Monthly is devoted to Mechanics, Manufacturing, Engineering, Rural and City Architecture, and improvements in all kinds of machinery and labor-saving devices. The practical directions about erecting cheap and convenient cottages, suburban villas and outbuildings, laying out grounds, embellishing the homestead, rural economy and making home a happy place, are not to be found in any other publication. A parent could not appropriate $1.50—the subscription price—to a better purpose than to order the *Industrial Monthly* sent to a son who is just beginning to act for himself. Send for a specimen copy, free, and read the club rates.

MECHANICAL TELEGRAPH INSTRUMENT

PATENTED MAY 31st, 1870.

For Students, Colleges, &c. No battery required. An ordinary key and sounder is placed upon a proper base. The sounder is moved by a lever under the base, connected with the key, making a perfect instrument for those wishing to learn the Art of Telegraphy. An expert could not tell, without examining it, that the instrument was not worked by a battery.

It should be introduced into every school and family where there are those who wish to learn the Art.

Hundreds of persons throughout the country desire to become expert Telegraphists, and are constantly seeking permission to practice in the various telegraph offices.

This instrument is an outgrowth of this pressing demand. The Inventor is himself a practical operator, now in active service. Operators and others wishing to teach or learn the Art, will be delighted with this instrument.

It can be placed anywhere, as it does not occupy a space more than six inches square.

Its cost is but $7, and there is no expense whatever to keep it constantly in working order.

We will send a copy of SMITH'S MANUAL, free of charge, with each instrument, to individuals or clubs. The instructions in this Manual are particularly adapted to those who wish to learn by sound.

Special and liberal terms to manufacturers.

Remittances can be made by certified draft on New York, Cleveland, or Pittsburgh, money by express, charges paid, post office order, or registered letter at our risk.

Parties ordering instruments, from points except well-known cities, will please give the name of county and State.

Price, $7. Silver Plated, Extra Finish, $10.

Address, D. W. PUTT & CO.,

These instruments can also be procured at the same price from L. G. Tillotson & Co., New York; Bliss, Tillotson & Co., Chicago, Ill.; Chas. Williams, Jr., Boston, Mass.; M. A. Buell, Cleveland, O.

WIRE IN BOND.

For the accommodation of the
SOUTH AMERICAN, CUBAN and MEXICAN TRADE,
we shall hereafter keep a stock of the Celebrated
"JOHNSON" WIRE,
both plain and Galvanized, in Bond, ready for shipment from New York.

PRICES AS FOLLOWS:

No. 9, Plain Annealed.....4½ cts. Gold.
No. 9, Galvanized.....5¼ "
No. 8, Plain Annealed.....4¾ "
No. 8, Galvanized..... 5 "

This Brand of Wire is the best in the world, and has been adopted exclusively by the Western Union and many other Telegraph Companies.

We also continue to import this Wire for use in this country, notwithstanding the high rate of duty imposed by Congress in the interest of the monopolists. Any amount of it can be seen at our store at all times. The import duty on wire is now two cents per lb. gold, and 15 per cent. *ad valorem*.

A SUPERIOR

Printing Telegraph Instrument,

FOR PRIVATE AND SHORT LINES.

The undersigned is now prepared to supply the improved and superior

PRINTING TELEGRAPH INSTRUMENTS

manufactured under the patent of Mr. J. E. SELDEN. This instrument has already been extensively introduced, and has given complete satisfaction to all who have adopted and used it. It is SIMPLE, RELIABLE, and not liable to get out of order; can be operated by any person of ordinary intelligence after a few minutes' instruction and practice.

PRIVATE LINES,

constructed in the best and most substantial manner, and on reasonable terms.

Favorable arrangements will be made with line constructors, telegraph employees, &c., for the introduction of the Printer.

For further particulars, terms, &c., apply to

SAMUEL J. BURRELL,

P. O. Box 6865. No. 50 Broad Street, (Room 14).

CHESTER, PARTRICK & CO.,

Manufacturers and Dealers in all kinds of

Telegraph Instruments and Supplies,

No. 38 South Fourth St., Philadelphia,

Keep in Stock, or will manufacture to order,

REGISTERS, SOUNDERS,
RELAYS, PLUG SWITCHES,
KEYS, REPEATERS,
LIGHTNING ARRESTERS, GALVANOMETERS,

and every variety of Instruments now in use.

Among the supplies constantly kept on hand are BATTERY MATERIALS OF ALL KINDS; INSULATORS, including BROOKS' PATENT, Paraffined; SCREW GLASS, PLAIN GLASS, and Chester patent GLASS AND RING, the last named having been pronounced by experts the best GLASS INSULATOR extant.

Also, SILK, COTTON COVERED, COMPOUND and IRON WIRES, from the best manufacturers in this country and Europe, among them the RENOWNED Chester A 1 Wire, which has proven by tests to be the very best in the market.

They are prepared to construct

FIRE ALARMS

for cities and private residences;

BURGLAR ALARMS,

for banks and public buildings; and contractors for construction and reconstruction of Telegraph Lines throughout the United States.

Also, Agents for the

Wilson Patent Electric

GAS LIGHTING APPARATUS,

for theatres, Halls and public buildings.

THE NONPAREIL TELEGRAPH APPARATUS.

(Patent applied for.)

This apparatus supplies a want which has long been felt, viz.: that of a SIMPLE and CHEAP

MORSE TELEGRAPHIC INSTRUMENT,

with all the necessary Batteries and other appurtenances in a CONVENIENT and COMPACT form.

By means of a switch, which is now placed on each instrument, they can be worked as desired, either as the open or the ordinary continuous, or closed circuits.

It is intended especially for the use of

STUDENTS, AMATEURS, AND OPPERATORS,

but will be found to be equally well adapted for use on

PRIVATE TELEGRAPH LINES,

or Short Lines of any description, which are not over three or four miles in length.

A NEW FORM OF BATTERY

is employed, which is compact, efficient, and economical, and especially adapted to the purpose for which it was designed. Each instrument will be accompanied by a

BATTERY, CHEMICALS, INSULATED WIRE

for connections, together with an

ILLUSTRATED BOOK OF INSTRUCTIONS,

which in itself forms a complete elementary treatise upon the ART OF TELEGRAPHY.

PRICES:

Single Instrument, complete, with Batteries, etc.....$8 00
Two Instruments, " " " " 15 00

Sent by Express on receipt of price.

Remittances may be made by Post Office Order, Registered Letter, or Draft payable to our order. Persons ordering Instruments will please write plainly, giving Post Office, County, and State, with instructions for shipment. Address,

F. L. POPE & CO.,

P. O. Box 6010. 80 Broadway, (Room 51,) New York.

THE NONPAREIL TELEGRAPH APPARATUS may be procured through the leading dealers in Telegraph Supplies throughout the country.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 7. NEW YORK, MARCH 1, 1872. WHOLE NO. 104.

PROFESSOR HENRY AND PROFESSOR MORSE.

LETTER OF PROF. L. D. GALE, OF WASHINGTON, D.C.

To Henry J. Rogers, Esq., Corresponding Sec'y, &c.:

DEAR SIR:—I have just read a letter from F. O. J. Smith, dated Dec. 11th, 1871, addressed to you, and designed to throw discredit on Morse's invention of the telegraph, the burden of which seems to be a rebuke to the designer of the monument, for elevating Morse to the apex of the monument, and claiming for Professor Henry, of the Smithsonian Institution, that high distinction.

The first question of an impartial inquirer is, to which of these gentlemen is the honor due? To ascertain this we will ask a second question. Was the subject of the invention a *Machine*, or was it a *New Fact in Science?* The former was Morse's, the latter was Henry's? The answer is, it was a *Machine.* Henry stated, that electric currents might be sent through long distances, applicable to telegraphic purposes. Morse took the facts as they then existed, invented a machine, harnessed the steed therein, and set the creature to work. There is honor due to Henry for his great discovery of the scientific principle, there is honor also due to Morse, for the invention of the ingenious machine which accomplishes the work.

Men of science regard the discovery of a *new fact* in *science* as a higher attainment than the application of it to useful purposes, while the world at large regard the *application* of the principle or fact in science to the useful arts, as of paramount importance. All honor to the discoverer of a new fact in science; equal honor to him who utilizes that fact for the benefit of mankind.

Has the world forgotten what Robert Fulton did for the navigation of waters by steamboats? It was he who first applied steam to propel a vessel, and navigated the Hudson for the first time with steam and paddle-wheels, and vessel, in 1807. Do we not honor him as the father of steamboats? Yet, Fulton did not invent steam, nor the steam-engine, nor paddle-wheels, nor the vessel; he merely adapted a steam-engine to a vessel armed with paddle-wheels. The *combination* was his invention. There is another example on record: Cyrus H. McCormick, the father of the reaping and mowing machine, took out a first successful patent, in 1837, and is justly acknowledged the world over, as the inventor of this great machine. Although 146 patents were granted in England previous to McCormick's time, they are but so many unsuccessful efforts to perfect a practical machine.

Yet, it is equally true that McCormick did not invent one original device used in his celebrated machine. The cutting apparatus, the device to raise and lower the cutters, the levers, the platform, the reel, the frame work, had all been used before McCormick's time.

But McCormick was the first genius able to put these separate devices together in a practicable, harmonious operation. The *combination was his* invention.

Morse did more, he invented the form of the various parts of his machine, as well as their combination. He was the first to put such a machine into practical operation, and for such a purpose. Who can question his title as the inventor of the telegraph?

Yours truly,

L. D. GALE.

Washington, D. C., Jan'y 12th, 1872.

INTERNATIONAL TELEGRAPH CONFERENCE.

SPEECH OF VISCOUNT VENOSTA.

The speech with which the International Telegraph Conference was opened in Rome, by Viscount Venosta, Minister of Foreign Affairs, was about as follows:

"At a not far remote period, politics was the exclusive employment of cabinets. Now, on the contrary, governments conceive it to be among their most earnest duties and cares, through their Minister of Foreign Affairs, and his agents, to watch over the development of commerce, and to make intercourse between nations easy, widespread, and quick. So it happens, that in addition to great political questions, which often enough yet engage the attention of statesmen, debates on much more peaceable but also of a more advantageous character take place on important subjects:—Postal facilities, Railroads, Telegraphs.

"Celebrated scientists, experts, and men of great executive ability have been called to the assistance of diplomats by profession, and this uniting of diplomacy with men who possess the priceless possessions of positive knowledge appears to me to be the introduction of one of the most fruitful innovations in the relations of nations towards each other. We can yet remember the time when each government thought itself to be in duty bound to strictly guard its boundaries against every new idea. Of all contrabands, that of ideas seemed to them the most dangerous. Now there are no more boundaries to thought; your Telegraph Lines encircle the earth in a net, whose meshes, becoming continually multiplied, represent in a certain measure, the nerve system of our planet.

"It is true, the Telegraph may be misused, it may serve the most reckless speculations; it is the most wonderful instrument for war, as for peace. This wonderful present to the omnipresence of human thought, does away in the most emphatic manner, with the causes of ignorance and error. The complete, continuous, instantaneous knowledge of men and things which are distant from us, prevents misunderstandings, and powerfully aids to the continuance of friendly relations among nations.

"In a certain degree united into a permanent association, you can, gentlemen, recommence the work anew in Rome, which you began in Paris, and continued with so much eclat and result in Vienna.

THE TELEGRAPHIC CONGRESS.

The telegraph conference which has lately concluded, was held for the purpose of the revision of the Convention of Vienna—a convention consisting of 67 articles concerning the international transmission of messages. It originated in Belgium, where a Conference was held at Brussels in 1858, and the original articles were drawn up, which were improved at a succeeding Conference held at Paris in 1865. It was then decided that Conferences should be held triennially at one of the European capitals. Vienna was chosen for 1868. It was there decided that the succeeding conference should be held at Florence, as the capital of Italy; but Rome having passed into the hands of the Italian Government, the Conference assembled there on the first of December last. All the European States, Luxembourg excepted, sent one or more delegates. Signor M. E. d'Amico, Deputy and Director-General of Italian Telegraphs, presided. The articles of the Convention are binding on all the contracting powers during the period between one meeting and the next, when any modification which may have suggested itself in the interval can be proposed. Any power not having joined the Convention can do so between the triennial meetings by accepting all the articles unconditionally. A claim put in by the great telegraph companies that they should be represented at the Conference, raised the question whether the Submarine Companies should be entitled to a *locus standi* outside the States from which they obtained their concessions.

As regards the great companies, after some discussion, the question being put to the vote, it was carried that the representatives should be admitted to the deliberations, but without the power of voting. The question of the neutrality of telegraphs in time of war was ably furthered by Mr. Cyrus Field, on the subject being drawn attention to by Mr. Neilson, of Norway. The President, however, having stated his opinion that the point could not be taken into consideration by the Conference, the subject was dropped. The resolution, however that—

"The Conference expresses the wish that the questions brought forward by Mr. Cyrus Field at the conclusion of his observations may attract the attention of the Governments," was passed.

Some interesting points with regard to the sending of messages in code, through the lines to India, were discussed. The principle of sending messages in code is that of making certain words represent complete sentences. By this method it is obvious that a message can be very much abbreviated, without at all obscuring the meaning to those who have the key to the code. The whole message is, in fact, a secret one, yet is so managed as to avoid being classified, and charged as such. The Indian delegates were desirous of charging these polysyllabic messages as messages sent in cipher. The majority of the delegates, however, were in favor of free trade, and insisted, not only that these messages should be charged as ordinary ones, but that messages sent in cipher should enjoy the same privileges. Major Champain

Digitized by Google

ineffectually urged that this was in reality encouraging the sending of secret messages, which were infinitely more difficult to send than messages containing a positive meaning to the operator.

The chief subject brought to the notice of the Congress appears to have been that of the inconvenience caused by the competition between the Indo-European lines. From 1864 to 1870 the Turkish was the only line to India. The constant complaints of irregularity in the transmission of messages by this route led to the formation of the Indo-European Company's line, via Kertch and Teheran, and finally of the Red Sea line.

According to Article 13 of the Vienna Convention, each Government is to be the judge on behalf of the sender, of the route by which messages are to be sent. The Indian Government having this power, promised the Red Sea line an equal share of messages, provided the service was properly conducted. It is alleged, however, that when the Singapore line was completed, its directors combined with the Red Sea Company, in defiance of the Convention, and obtained for it the monopoly of the messages by printing on their forms "via Red Sea," and refused to send messages by any other route—the Red Sea having at the same time its share of the messages from the Indian Government, as agreed. To prevent this arrangement an amendment was carried to Article 13, allowing the sender to choose his own route, by writing the direction on the message.

NEW YORK STOCK REPORTING.

There are four (4) Morse operators employed at the Stock Exchange, known as Reporters, the duties of one being confined exclusively to the transaction made on the first and second calls, and on Government Bonds.

The duties of the other two are confined to the reporting of sales, bids, changing of quotations, &c., during the hours of the Board, and which are made outside of the two calls.

There are four (4) sets of instruments used, each set being simply a relay and key—one up stairs in what is known as the "Government Room," where all transactions in Government Bonds are made, and the other three in the "Long Room" down stairs, where transactions in every description of stocks are made, as well as of State Bonds and securities.

These four (4) instruments are connected by one circuit leading to the main office of the Gold and Stock Telegraph Company, 61 Broadway.

The instrument in the Government Room is in close proximity to the President's desk, where the reporter can see and hear all sales made, and which he transmits almost simultaneously with the announcement of the sale, in fact, almost before it has left the President or Vice-Presidents' lips.

The three (3) instruments in the "Long Room" (lower) are situated, one immediately in the rear, and on a level with the President's desk, this being used only for the transactions on call; the other two, are placed one each side of the room, one reporter remaining on each side, thus dividing the work, attending exclusively to certain stocks, and prevent the reporting the second time of the same sale or quotation, which would be the case, if they were to run from side to side, while both were on duty. The reporter mingles in with the "Pools" on his side, watching each one closely, keeping his eyes and ears open, and as soon as a sale is made, reports it at once to 61 Broadway by the stock wire. No sales of less than 100 shares of any stock is reported, unless by request, and that of a majority of the members present. The Reporters are constantly on their feet, the reporting done standing, no calling is necessary—the operator simply runs to the instrument and reports, for example, "W. U. 500, 70⅝; R. I. 200, 110¼. U. P. 100, 28—or quotations; W. U. 66½ @ ⅝ R. I. 110¼ @ ½; U. P. 27½ @ 28.

No response is necessary, unless the operator at 61 doubts the figures, and asks if correct, which is done in as few words as possible, thus giving the other reporter, and the one on call, no delay in reporting from his side, or the sales on call or Governments.

There is one Morse stock circuit from the Exchange to 61 Broadway, on which the four (4) instruments mentioned are in circuit.

At 61 Broadway, in an office which is inaccessible to any one with the exception of those connected with it, except through the rooms of the officers of the Company, an operator is constantly on hand during the session of the Board.

As each sale, bid, or change in quotations is announced, he immediately calls out, and at the same time writes down on a large form, which is renewed every day, the sale, bid or change in quotation, as he calls out each sale.

There is a printer who transmits it at once on a return wire back to the Exchange, where it is printed, and where it is open for inspection to all the members of the Board. By this means they are enabled to see if any mistake occurred in the reporting from the "Long Room."

At the same time that this is printed, the transmitter also communicates to the offices of several hundred subscribers of the Gold and Stock Telegraph Company, which of course appears printed; and every banker and broker is enabled to see how matters stand at the Board, without leaving his office, or sending to ascertain. These reports are also transmitted (printed) at the Commercial News Department at the same time, as well as at the Cotton and Produce Exchanges, also to various hotels, and most of the Banking houses. In fact, the printing instruments are found every where. These instruments are all connected by one circuit.

There is also another wire connecting these different places, as well as running into a number of banking establishments, 61 Broadway and the C. N. D.* giving all changes in gold by means of the indicator. This circuit runs from the "Gold Room" and is controlled by the secretary of the Gold Board, who personally transmits all changes by means of the magnetic indicator, thus securing to a certainty, official and correct changes in all gold operations. The services of this officer of the Gold Board have been secured by the Gold and Stock Telegraph Company to attend to this important duty.

From 61 Broadway to C. N. D., is a circuit known as the Stock wire, by which all operations of the Board are transmitted instantly. There are the two regular calls, 10:30 A. M. and 1 o'clock P. M., (1st and 2d call). State bonds twice a day; first and second call of Governments, and also what is known as street sales of Governments and stocks every half hour. These are immediately transmitted by the C. N. D., over thirteen (13) different circuits to every city in the United States and the Canadas, simultaneously, to the agents of the department, who immediately furnish to their subscribers, as well as transmit by the printers, where the company have introduced them.

The regular weekly Bank statement is transmitted every Saturday in the same manner. The C. N. D. also receive from London, Liverpool and Paris, three regular reports daily, with additional reports thereto, giving intermediate changes in the European Markets. The reports some days reach to the number of twelve (12) or fifteen (15) from the principal English markets, also two or more reports from Frankfort, and Antwerp, Bremen and Hamburg.

These reports are immediately placed in cypher and transmitted over the 13 different circuits from the C. N. D. for distribution to its subscribers in all parts of the United States and the Canadas.

In the transmission of all stocks, Governments, States, &c., from C. N. D., the gold quotations are given.

Running from the C. N. D. to the New York Cotton Exchange and the Produce Exchange are four circuits, two Morse, two printers. On these two Morse circuits are received the New York Cotton and Produce reports, some 30 or 40 of the former, and 25 or 30 of the latter. These reports are received in cypher, and are immediately forwarded by the C. N. D. over its 13 circuits, with no delay perceptible, the mere transfer from one instrument to another only being necessary.

The two printers are used in transmitting to the Cotton Exchange, and Produce Exchange, as well as to all subscribers in this city simultaneously, all the domestic Cotton and Produce Markets of the United States and Canadas, as well as those of London, Liverpool, Paris, Hamburg, Antwerp and Frankfort, and various other European markets. These reports are received in cipher, translated and transmitted over the printers.

At the Cotton and Produce Exchanges, two persons are employed at each, one as reporter, and one as operator, the reporter putting all in cipher before transmission. Besides transmitting to C. N. D., both these Exchanges can work direct with a number of prominent distant points.

SIEMENS' DYNAMO-ELECTRIC LIGHT.

A series of experiments was made at Sheerness, with a view to ascertain the applicability of Siemens' Dynamo-electric light to torpedo services in time of war. The principle on which the apparatus is constructed is that of causing the rotation of an indication coil of a peculiar construction, known as Siemens' armature, between the poles of a soft-iron electro-magnet. The feeble permanent magnetism which the soft-iron core of the electro-magnet has imparted to it when the machine is first made, causes currents to be induced in the wire of the rotating armature; these currents are caused to pass through the wires of the electro-magnet, thus increasing its power, and consequently also increasing the amount of electricity set in motion. The strength of this current of electricity is proportional to the dynamical force employed to rotate the armature. The current thus induced is caused to pass into the coils of the electro-magnet of a second machine of similar construction to the first, but of larger dimensions; the armature of this second machine is driven by the same engine that drives the armature of the smaller one, and is caused to rotate about 800 times a minute. It is the electricity from this second machine that produces the electric light by its passage between carbon points. The light in the experiments made when reflected by a parabolic reflector was of the most brilliant description—in fact, it was sufficiently clear that no objects of any appreciable size, such for instance, as an enemy's boat engaged in interrupting communication with a line of torpedoes a night, could have approached within a mile or more of Sheerness, without being sufficiently conspicuous to be fired at, and consequently driven off. The idea of causing the return of the current upon itself in the machine, was, we believe, announced simultaneously by Sir Charles Wheatstone and Mr. Siemens

A BRIBE—CASH IN ADVANCE.

GENERAL OFFICE OF THE
METROPOLITAN TELEGRAPH INSTITUTE,
No. 213 NORTH THIRD STREET,
Opposite Post Office,
ST. LOUIS, MO., Dec. 11th, 1871.

DR. SIR.—We have from time to time, say twice or thrice a month, a good, competent student, who can send and receive readily by sound thirty words per minute. They also understand R. R. business as we have them practice in an office on the St. L. & I. R. R. for some time before pronouncing them competent. They can easily take charge of a night office or small day office, and would work for $40 per month. We have such a one at present. If you would chose to give one of my pupils the preference whenever you should have a suitable opening, I would pay you (as a present which would be strictly private and confidential between ourselves) the sum of fifty dollars cash in advance. If you think it would be an object to you the matter can be easily arranged satisfactorily to yourself. Please give me an early reply.

Yours Respectfully,
P. MCEACHERN.

The above is a bona fide letter, the original of which we have before us. We had occasion to denounce a similar institution in Sandusky for like practices. What charges are made to permit fifty dollar bonuses we cannot imagine. It is a false and injurious system. An honorable institution cannot resort to it. We have never joined in the cry against telegraph colleges as such. They can instruct as perfectly as instruction is possible without actual employment on business lines. Some have done so well and thoroughly. By proper arrangements there is no reason why first class operators cannot be thus instructed. But this system of enticement, pledging an office to each student, and offering bribes for their employment, has made them all suspected, and caused many to suffer cruel disappointment.

THE TRANSANDINE TELEGRAPH.—A double line of telegraph is at present being constructed across the Andes. Thirty miles of this line, which will pass over the snow-covered cordilleras, will be constructed of two copper-sheathed cables. It is expected that the line will be completed early in the spring.

THE ATLANTIC TELEGRAPHS.—A memorial has been presented to the Prime Minister by the Council of the Society of Arts, urging the importance of the Government at once securing by purchase the ocean telegraph cables connected with England, and thus combining the external with the internal telegraph service under the management of the Post-office. The memorialists call attention to the expense and uncertainty connected with the present arrangements, and the need for a very wide extension of the submarine telegraphic system to our various colonies and naval stations. It is further pointed out that the delay in acquiring the internal telegraphs has added seriously to the cost of purchase, and that the great bulk of that purchase-money may be properly considered as a penalty for the Governmental neglect after the necessity of the measure had been demonstrated. The memorialists consequently urge the completion without delay of a proper external as well as internal system of public postal telegraphy by the compulsory purchase of all the existing submarine lines of cable, and consolidating the same with the general postal system of this country.

POST OFFICE TELEGRAPHS.—A publication, entitled "The Office Code Book," has just been printed for the Post Office authorities, for the guidance, in the first instance, of telegraph clerks; although probably the information contained in it will at an early date be printed for the use of the public. It contains a list of all the telegraphic stations in the United Kingdom, and of the railway stations at which telegrams are collected and delivered by the railway companies on behalf of the Post Office, as well as a statement of the hours during which telegraph offices are open for business. It gives, moreover, the names of certain money-order offices in the country not yet opened for telegraphic business, with the name in each of these, of the nearest telegraph office, and its distance from the money-order office. The post-office authorities have also prepared stamped postal telegraph cards, for public use. These cards will be issued on and after the 5th of February, at 1s. each, or in packets of 20 for £1; and it is believed, that in a number of cases they will be more convenient than the ordinary stamped message form. They are intended for the use of persons who cannot, or do not desire to send messages to the nearest telegraph office, but who may be content to deposit them where they will be carried free of expense, to an office from which they can be sent by wire. If deposited in a pillar-box, wall-box, or ordinary post-office letter-box, they will be carried to the telegraph office to which the letters posted in the box are sent, on the next clearance of the box. The 1s. stamp on these cards will cover the cost of transmission of a message of not more than twenty words, within the United Kingdom, Scilly, Orkney and Shetland Islands excepted—the Channel Islands and the Isle of Man, as well as of the delivery of the message by special foot messenger within a mile of the terminal telegraph office or within the boundary of the postal delivery of that office, even in cases where that limit exceeds one mile.

JAPAN.—It is announced that the land line of telegraphy between Yedo and the North will be commenced forthwith. There will be a cable laid across the Straits to Hakodadi; and it is believed that within the next fifteen months Hakodadi, Yedo, Yokohama, Kobe, and Nagasaki and several intermediate places will be in telegraphic communication.

BATTERIES.—The following are some recent determinations of the electro-motive force of batteries, by M. Beetz, obtained with great accuracy:—

Bunsen's element	1·779	volts
Grove's "	1·684	"
Lelanche's "	1·167	"
Daniell's standard	1·000	"

The following are the results obtained some time since by Mr. Latimer Clark:—

Daniell (standard)	1.079	volts
Daniell (telegraph)	0·978	
Lelanche "	1·481	"
Bumen "	1·888	"
Grove "	1·956	"

ACCORDING to advices from New York, the American Atlantic Telegraph Company will probably begin at an early day to lay a cable from the extremity of Long Island to a point on the English or Dutch coast. A proposition is also at present before the Legislature of California, to grant permission to a company to lay a cable from San Francisco to a port in China. The Georgia Legislature has also granted to certain persons, the privilege of laying a cable from that coast to a point in France; but as Congress has jurisdiction beyond low water mark, it is doubtful whether any advance can be made until the matter has been acted upon by Congress.—*Mechanics' Magazine.*

ELECTRO-AUTOMATIC APPARATUS.—The members of the telegraph staff, D. Enrique Iturriaga, and D. Vicente Villareal, have invented an electro-antomatic telegraph apparatus which, according to the opinion of competent persons who have seen it work in the central station, is destined to bring about a revolution in the telegraph world. The commission appointed by the Post and Telegraph Director-General for the examination of the said apparatus, have given an account highly gratifying to the inventors; the minister of that particular branch has been informed of the importance of the matter and also of the scanty resources of the telegraph clerks preventing them from carrying out their project. The minister, in consequence, have had the necessary means placed at their disposal, so that Spain may not lose the honor of having inaugurated a useful reform in the transmission of communications.

BATTERIES.—Some interesting experiments have been lately made by M. du Moncel on the relative size of elements in an ordinary battery. He experimented with two Bunsen cells of equal size, but the elements were arranged differently. In the one, the negative element consisted of two plates of carbon dipped into nitric acid in the cell itself. The zinc, or positive element, centimetres, well amalgamated, was placed in the porous vessel containing acidulated water. The second cell contained two plates of zinc and one of carbon, the liquids being in all respects similar. The surface immersed was as 1 to 2.43 in the two cases. The electro-motive force of the currents as obtained from a tangent galvanometer were relatively 84° 10′ and 78° 5′, the smaller surface giving the greater force. The consumption of zinc was 32 and 38 grammes. From this it would seem that there is a gain with a smaller positive element over a larger, and also when the same element is smaller than the negative. These results are borne out by previous experiments of MM. Ruhmkorff and Delaurier, the former finding that when the zinc of a bichromate of potash battery was immersed one-fifth of its height, the battery gave out during the six hours an intensity that agreed with the total immersion of the metal. The result of such experiments tends to prove the use of a small surface of zinc, and the consequent economy for telegraphic purposes. Lelanché cell, now so much in use for telegraphic purposes, exposes but a small amount of zinc, and its electro-motive force is considerable, being nearly 50 per cent. more than the ordinary Daniell.

ELECTRIC CURRENTS OBTAINED BY THE BENDING OF METALS.—P. Volpicelli.—Metals when being bent or twisted give rise to the development of an electric current, but copper exhibits this phenomenon in the highest degree. Lead, although not an elastic metal, also gives rise to the generation of an electric current, thus exhibiting an instance of the conversion of mechanical force into electricity; the electric currents thus produced are not perceptibly due to the development of heat due to the action of bending or twisting. When the bending is accompanied by the tearing asunder, or, rather, the distending, of the two ends of the metallic wire, a current is produced in an opposite direction from that obtained by putting the two ends nearer together; by increasing or decreasing the velocity of the bending, the intensity of the electric current is also increased or decreased. A metallic wire made of various metals soldered together produces, other conditions being the same, a less intense current by bending than when the wire is made of one and the same metal.—*Chemical News.*

MEMOIR ON THE CHEMICAL EFFECTS DUE TO THE CALORIFIC ACTION OF POWERFUL ELECTRIC DISCHARGES.—M. Becquerel.—After describing minutely and at length his apparatus and method of experimenting, the eminent *savant* states that the reduction of the oxides of silver, lead, tin, and copper is obtained by mixing these substances with some charcoal-dust, and exposing them to the heat derived from an electric discharge (powerful induction apparatus) in U-shaped tubes, while the oxides of nickel, cobalt, iron, and chromium, similarly mixed with charcoal-powder and some powdered sugar, and put into a platinum crucible, are also reduced; silica and alumina are fused, and sometimes small crystals are found in the fused mass.—*Chemical News.*

CONDUCTIVITY OF PRINCIPAL WESTERN WIRES.

The following tests have recently been made of the wires which comprise the main through Circuits between the principal Western cities, and show that the resistance to conduction is low in all of them, and that there are few, if any, bad joints:

CHICAGO CIRCUITS.

No. 1, New York	17.3	ohms	per mile.
2, "	19.1	"	"
3, "	10.8	"	"
4, "	20.5	"	"

REWARD FOR ELECTRICAL IMPROVEMENTS.

By a decree, dated April 18, 1866, of the Minister of Public Instruction in France, a prize of 50,000 francs ($10,000) was offered for the most useful application of the voltaic pile, the period for competition to expire in April, 1871. From a report of the minutes presented by the President of the Republic it appears that candidates are few in number, and that, in the opinion of the *savans* to whom the memoirs were submitted, none is of sufficient merit to have earned the prize. By a decree of the 29th of November, the competition is now extended for another period of five years, to terminate on November 29, 1876.

THE POSTMASTER-GENERAL AND MR. SCUDAMORE.—The Postmaster-General has condemned Mr. Scudamore's over-vigorous action in the matter of delaying private telegrams. There has been some confusion in this case between the powers of the Post-office and that of the Home Office, and Mr. Graves has argued that the Postmaster ought to have the same rights as regards telegrams that the Home Secretary has as regards letters. But all necessary rights of this kind are already vested in the Home Secretary as the Minister specially charged with the maintenance of public order. Any letters or telegrams by which, in the opinion of the Government, this would be seriously threatened, would at once be stopped. What the Postmaster-General is charged with is the transmission and delivery of such written or telegraphed communications as the public choose to intrust to him. In Mr. Scudamore's case there was the further irregularity that this kind of power was assumed not by the Minister who can be called to account in Parliament, but by the chief of the permanent Staff.

FAMILIAR TELEGRAPH TALKS.

Before speaking of the local battery, we had better finish the operating table. There are a good many interesting points there which will bear talking about.

THE MAGNET.

The magnet is the operator's capital. It is simple enough, yet demands conditions of structure and care.

It is a very important matter for an operator that the core of his magnet be well annealed, and of proper size and length. A poorly annealed core, by which is meant the imperfect process of softening the iron, is a great obstacle to the comfort of an operator's work. To secure a good core, preference is given by some to iron which has been hammered. Alfred Vail used to make his cores out of old chains, horse shoes, and articles which had been beaten into shape. We do not know how particular makers now are in this respect, or indeed how much real advantage was attained by it. The idea was to increase the amount of fibre as compared with the crystal portion of a common iron rod; any one breaking an iron rod will see the difference between the centre and edge; the centre has little cohesion or compactness; the edge is close grained, fine, powerful. To anneal the core properly, all work should be finished upon it before it enters the fire. The fire should be so made that by covering with ashes or slack, its life may be prolonged for a day or more, and die out very slowly. When taken out, no hammer or file, or chisel on the turning lathe should be used upon it; and when put in its place, and in use, the armature should never be allowed to touch it. Every blow it receives, every violent current passed through it, tends to harden and make it retentive of magnetism, instead of giving it up freely and fully as in its perfectly annealed state. Hundreds of operators know how much trouble they have had with their magnets in having to adjust their armatures so far from the cores to get rid of their permanent magnetism, as to render the reception of messages tedious and uncertain. Electro magnets will, we think, be made so as to permit the cores being easily removed and re-annealed when necessary. All Western Union magnets are now so made.

The winding of a magnet with the silk-covered wire is as if it were wound on a straight shaft, and then bent. If the two bobbins of a magnet were wound in the same way or direction, they would neutralize each other. There has been a good deal of controversy as to the comparative advantages of a long over a short core. Many contend that inasmuch as the coils of the wire nearest the core, when charged with the current, are the most powerful, that a long core upon which this maximum power could be applied, is best. In theory this seems true and reasonable; yet what is gained by the nearness of the current is lost apparently by the separation of the poles—at least experience has seemed to establish the fact that comparatively short magnets are the best.

Judge Caton has constructed a magnet by which he not only preserves a short core, but secures the advantage seemingly due to one made long. He uses four bobbins, acting on a double armature, or an armature at each end of the arm on which the armatures are usually placed. This gives two cores, two faces, and with an amount of wire not greater than on an ordinary magnet, yet disposed so as to be near and acting sharply on the core. Many claim this magnet to be superior in prompt magnetization and power, *i. e.*, the current acts promptly upon it, and the action is clear and sharp. Ordinarily, magnetization is comparatively slow, as compared with its departure. In the amount of wire wound upon a magnet, great mischief has heretofore been done. To secure apparent power, the wire has been made very fine, and the convolutions not only made very close, but multiplied beyond all reason. This was the case with the Bradley magnet, once thought so excellent. So great was its resistance that, when Mr. Varley tested the various magnets in use, he found a Bradley exhibiting a resistance of 906 ohms, or equal to seventy miles of line wire! He had on convolutions of wire which only acted as an obstruction, and which never gave a unit of power to the core. These were simple obstructions, and some magnets were worse than Bradley's! The wire also was very small. The size of wire on a magnet, indeed, should correspond to the length of the circuit and the number of its offices. For a long circuit the wire may be fine, without harm. The ordinary number of wire used is 32. The following are the items of a magnet, as now made:

Length of bobbin	1⅝ inches.
Diameter of core	⅞ "
Diameter of bobbin	1⅛ "
Size of wire	32.
Resistance	125 ohms.

It is of great importance in winding the wire on a core, that the first layer be carefully seperated from it, and yet proximity preserved. There is the utmost danger when the silk covered wire is laid, without intervention of any other substance, against the core. Mr. Varley found, by testing the magnets in the main operating room of the New York office, that out of sixty-four magnets in use, eight had had the silk next the core burned, supposably by lightning, and the core had become metallically connected with the main wire. This is especially harmful in way offices where locals are placed in damp places, as they often are. It only requires the armature to touch the face of the core to connect the main and local wires, and thus cause an escape. In every case it exposes the main current. Magnets in this condition are easily detected by applying one local wire to the entering main wire post, and the other to any part of the core.

Culley has two notes on magnets, which we give:

"In four magnets, wound proportionately, 2, 4, 8, and 16 inches long, and respectively ¼, ½, 1, and 2 inches in diameter, placed at distances of 6, 12, 24, and 48 inches, the attractive face will be the same.

"A hollow core is less powerful than a solid one; but if its ends are made solid there is no great difference. The poles of an electro-magnet should never be smaller than the core."

A DAY or two since, a man not over and above familiar with the dark ways of telegraphing, went into one of the offices in this city with a dispatch, which he insisted on having sent off immediately. The operator accommodated him, and then hung the dispatch on a hook. The man hung around some time, evidently unsatisfied. At last his patience was exhausted, and he belched out: "Ain't you going to send that dispatch?" The operator politely informed him that he had sent it. "No yer ain't," replied the indignant man; "there it is now on the hook."—*Commercial*, Bangor.

AUTOGRAPHIC TELEGRAPAH APPARATUS.—M. d'Arlincourt.—This paper contains a detailed account of the description and mode of manipulating a kind of apparatus which has been tried in France on a telegraphic line of which the two termini are 900 kilometres distant from each other; the velocity of transmission is the same as Hughes's apparatus (forty dispatches per hour); the results are said to be satisfactory in all respects.—*Chemical News*.

EVANSVILLE, Ind., January 23, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—In your remarks in the JOURNAL of January 15, under the head of "Incivility," you say "We must speak of our experience sometime," &c. I, for one, beg that you will give us more of your experience, through the JOURNAL, for I know there is no one better qualified to instruct us. I have amongst my *treasures*, your Circular, dated Louisville, Ky., June 1, 1852. "To the gentlemen connected with the offices of the United New Orleans and Ohio and People's Telegraph Lines." I was one of the operators who had the pleasure of obeying the orders in that Circular, and it has been my guide in governing those under my superintendence. I hope all Telegraph officials will read the article in JOURNAL of 15th, and follow your advice. God bless you in your efforts in our behalf, is the prayer of,

Yours truly,

N. M. BOOTH, Supt. O. R. T.
and Manager W. U. Office, Evansville, Ind.

To the Editor of the Journal of the Telegraph.

DEAR SIR:—I am frequently asked the cause of the humming noise heard at the poles and in the offices along a Telegraph line, but am unable to answer it, and would solicit an explanation in the next issue of the JOURNAL. I have noticed it in all kinds of weather, both Winter and Summer. I formerly worked on a line running North and South, and noticed the noise was much louder there, than on lines running East and West. An explanation in the next number of your JOURNAL will be thankfully received, by a YOUNG OPERATOR.

Simply vibration caused by the wires. As the prevailing winds are from the West, a North and South line will vibrate most.

DEAR SIR: Will you please give me the date and year that the first telegraph line was put in operation, and from what points it run; also the age of Prof. Morse. W. D. WILSON.

Washington to Baltimore, 1845. Prof. Morse was 80 April 27, 1871.

TELEGRAPHY.—W. C. Barney, Washington, D. C.—*Feb.* 6.—This improvement in means of transmitting telegraphic messages consists in sending the message over the ground line from a transmitting to a receiving instrument before it has made a transit of the wire; that is to say, by placing the transmitting instrument between the positive pole of the battery and ground, and connecting the air-line with the negative pole of battery. Also, in a novel method of arranging the message-receiver or message-repeater between the ground wire and negative pole of the battery.

ELECTRO-SIGNALING APPARATUS FOR FIRE-ENGINES.—W. H. Mumler, Boston, Mass.—*Feb.* 6.—Among the more notable points of this invention is a novel process of signaling from the hoseman to the engineer or foreman of a steam fire-engine, by means of electro-magnetism. Also, the combination with a fire-engine and the leading hose thereof of a battery and signal mechanism located on the engine, and conducting-wires leading from said battery and signal mechanism to the leading hoseman, and a suitable circuit-closer at or near the "butt" or discharge-pipe, for the purpose of transmitting signals from the hoseman to the engineer or foreman. Also, in combination with each length of the leading hose, a cable consisting of one or more insulated wires attached thereto, either inside or outside of the hose, and provided with suitable couplings for uniting two contiguous lengths, and insuring a connection between the same.

ELECTRO-MAGNETIC APPARATUS.—G. Little, Rutherford Park, N. J.—*Dec.* 26.—In this apparatus an oscillating armature and two helices are connected to the main line, and used in combination with a local current connected with one of the helices. The invention also includes an oscillating armature upon a fulcrum connected with the cores of two electro-magnets, in combination with two electric currents connected with the helices of said magnets. A supplemental combination of devices is covered by an additional clause of the claim.

THE PRESERVATION OF POLES.

The life of a telegraph pole has usually been set down as an average of ten or twelve years. Practically, by cutting down and resetting, they last some years longer. Even with this allowance, it must present a serious item of regular prospective outlay, that in a line of one hundred thousand or one hundred and twenty-five thousand miles, ten thousand miles, or three hundred thousand new poles have to be provided and planted each year. The subject has engrossed much attention also in reference to railroad ties, the consumption of which is enormous. It is clearly one of the most important practical questions how these may be preserved.

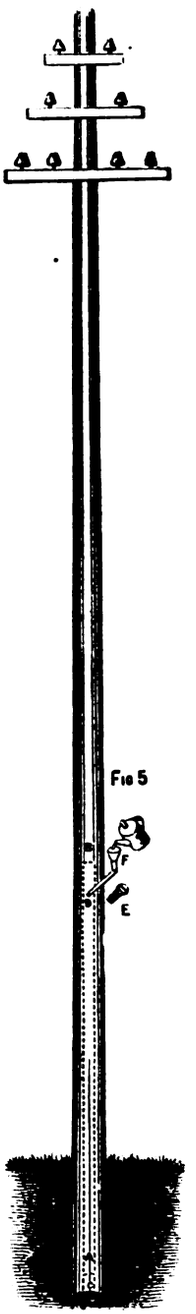

FIG 5

Our old friend, Col. E. Webb, offers a most simple, and yet, from the testimony presented, a most effective check to this decay. He has secured an auger capable of boring a pole or log to any required depth. Into this is poured, without either heating or pressure, an inexpensive liquid, which, by its own action, permeates the whole body of the wood, taking the place of the natural sap, and doubling or more the life of the material into which it is thus infused. As the sketch shows, the poles being bored before planting, and which does not at all weaken them, the liquid can be inserted after erection.

January 13, 1872.

To the Editor of the Journal of the Telegraph:

Money and time would be saved to our Company, if, in explanation of errors, managers would send *copies* of missing messages.

For instance, I mail my list of totals to another office. It is returned, saying, "Check you on ——. Signed ——. Date, ——." And I then have to request a *copy* of the message, which should have been sent before, and a delay of two weeks occurs in case the difference is with a California office.

R. R. M.

WATERTOWN, N. Y., Feb. 19, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—I would like to inquire whether Mr. Orton's proposition, to donate one hundred dollars as each death occurs, applies to all members of the Association, or only those in the employ of the W. U. Company. If it does not, will we that work for other companies, leave nine hundred or one thousand dollars to our friends, when we "shuffle off this mortal coil."

Yours truly,

DEXTER VAN OOSTRAND.

ANSWER.

We answered this in our last. The Western Union Telegraph Company cannot be expected to give one hundred dollars to the employee of another company. Every Telegraph Company must do its own benefactions for its own men. It is an *addition* to a "thousand dollars," not to make up that amount.

THE following occurrence is vouched for as taking place at Carlsruhe, dated Dec. 7th:

An aged mother came last Saturday to the telegraph office carrying a dish full of saurkraut which she desired to have telegraphed to Rastadt. Her son must receive the kraut by Sunday. The operator could not convince her that the telegraph was not capable for such a performance.

"How could so many soldiers have been sent to France by telegraph" she answered, and finally departed grumbling that on our railroad everything was asked.

MEASUREMENT OF THE VELOCITY OF CANNON BALLS.

A very ingenious instrument, known as Noble's Chronoscope, is used for measuring the velocity of shot during its transit through the gun. The tube of the gun is fitted inside at certain intervals with metal rings (to the number of six or eight), the outside margins of which are sharpened into knife edges. As a shot passes along the tube and through these rings, the edges of the latter are jammed down upon, and made to cut through, the ends of various insulated wires, one of which is placed under each ring. Each of these wires is connected with an electric battery, and, as one wire after another is cut through and the insulation removed, an electric current passes, and a number of electric sparks follow one after another, according to the number of the rings and wires. The recording of signals is accomplished by means of a series of metal disks, one in connection with each, which are made to revolve at a certain known velocity. The surface of the disks is of polished silver, coated with lampblack. As soon as a wire is cut by the passage of a shot, a spark hops over to the recording disk, removing a little of the lampblack coating, and thus marking the place by leaving a bare minute spot of bright metal. From the relative position of the successive spots on the disks, and the known velocity at which they revolve, a simple calculation determines the velocity of the shot. A shot usually takes from one two-hundredth to one three-hundredth of a second to traverse the whole length of the bore of a large gun, its speed being somewhat slow when passing the rings, and increasing as it approaches the muzzle of the gun. From the extreme delicacy of the instrument, the calculation can be made with precision to a millionth part of a second, and the velocity determined with the greatest accuracy.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JAMES D. REID, Editor,

Executive Rooms, Western Union Tel. Co.,

145 Broadway, New York.

NEW YORK, MARCH 1, 1872.

DISCHARGED FOR DRUNKENNESS.

Once a month or so there appears on our desk a manifold copy of the official report of discharges from the service. We have never published them. We fear to put the damning publicity to a weakness which calls as often for pity as for reproach, or hold up to scorn those who by patience and gentleness may be saved. The discharge is a necessity. No drunken man should ever handle a message, and a careful executive might even exact as the qualification for employment that rum and all its relatives be foresworn. But we prefer that the discharge be not complemented with the published shame. The lapse is sometimes the fall in a keen struggle. God only knows how keen and fierce the struggle sometimes is.

In Mrs. Stowe's "Wife and I" there occurs one of those stirring passages regarding this degrading vice which reveals its desperate tyranny. It is Bolton giving his reasons why he dare not marry:

"One sip would flash to the brain like fire, and then, all fear, all care, all conscience would be gone, and not one glass, but a dozen would be inevitable. Then you might have to look for me in some of those dens to which the possessed of the devil flee when the fit is on them, and where they rave and tear and cut themselves until the madness is worn out. This has happened to me after long periods of self denial and self control and illusive hope. It seems to me that my experience is like that of a man whom some cruel fiend condemns to go through all the agonies of drowning over and over again—the dark plunge, the mad struggle, the suffocation, the horror, the agony, the clutch at the shore, the weary clamber up steep rocks, the sense of relief, recovery, and hope, only to be wrenched off and thrown back to struggle, and and strangle, and sink again. If I had fallen dead after the first glass of wine I tasted, it would have been thought a horrible thing; but it would have been better for my mother, better for me, than to have lived as I did."

This picture of a noble man, who knew his weakness and his enemy, is only one of many such, not always so intense, but dark and dread with ever-constant danger. It may be a voice to some young man who reads it as he is about to yield to the first invitation to drink that, which may be, within him, like the flames of hell. Let the cursed thing alone, young men. The bright water that gurgles up from the earth or glistens down the mountain-side is for all men health and hope and happiness and life.

WHAT IS AN INVENTION?

If this question is properly answered, it will take from the field of polemics a great deal of misunderstanding and misconception, and prevent many an angry discussion.

We answer the question, then, in the first place, negatively. It is *not* the discovery of a principle in nature. The principle is in existence before its discovery. The discovery of a hitherto hidden principle, however, confers honor on the discoverer, as in the case of the discovery of the principle of voltaic electricity, the bringing forth for application of an important scientific fact not before known. Invention is the application and successful adaptation of the discovery, by means of known appliances, to the production of a certain novel result or results. In fact, it is the *combination* of these known appliances, with or without any new discovery, or with further discoveries, which is, emphatically, INVENTION. Every combination of parts, to whatever extent these parts may be in common use, such as wheels, levers, springs, &c., put into form for the purpose of producing a special effect, is an invention. The patent laws recognize the distinction between a "discovery" and an "invention." The former is not the subject of a patent; the latter is. In the publications of the French Academy there is a department, "Applied Physics," which, by its title, recognizes this distinction, and under this head is given, in the *Comptes Rendus*, the invention of the telegraph. Mr. Morse, in his speech at the banquet given him in New York, at which the eminent Chief Justice Chase presided, distinctly announced that "*invention is combination*," and it cannot be more accurately condensed than in this brief sentence. "It is only," says Morse, "when "the nature of *invention* is properly understood, that "the justice of the ascription of honor to the indi- "vidual inventor is perceived. *Invention is, emphati- "cally, Combination, an assembling or putting together "of things known, whether discoveries or other inven- "tions, to produce a new effect, to create a new art.*"

SOME year or more ago, we wrote an article for the JOURNAL, which we indited on the sill of a farm house window in western New York, whither we had gone for the benefit of buttermilk and fresh air. Its topic was *Automatics*, upon which we dilated with all the poetry inspired by churns and sheep and green fields. We were not very discriminating in our eulogy; how could we be when the sun was automatically warming us, and the hens were automatically laying eggs for us, and the farm cat automatically rubbing her brindled sides against our summer trousers? And so it happened, that not knowing the automatic divinity which with buttermilky joy we sung our sonnet to, all the automatics fancied we meant each one of them—Bain, Wheatstone, Hummiston, Little, Craig, every soul of them. And we had a sad time of it to get these damsels righted, and to get other people convinced that we did not mean them at all. Of course they were all mad, for they all wanted a good looking man to court them, and they were willing to accept us, but Barkis wasn't. Barkis means us. Our automatic lady indeed, was a creature largely of the imagination, although a specimen of the race existed in Europe, leading a lowly and poorly developed life. The system we had then in mind was the autographic telegraph, a vastly different thing from the punched and ribbonly female who has made such a fuss and done so little in the city of New York.

We cannot help thinking that the autographic system of transmitting messages must some day form a feature of American telegraphy. It is certainly a desirable possibility to be able to transmit a message exactly in the chirography of the writer, so that not only will the recipient recognize the hand that wrote it, but transmission be utterly relieved of the least chance of error. Our system in America has not been ripe for this, perhaps, and it will have to take the place of all luxuries, and educational embellishments, coming after all useful and necessary things have been provided. So far, the processes to accomplish it have been too slow, and therefore valueless. Attention, however, seems to have rewarded a European electrician, who has recently exhibited machinery transmitting, successfully, messages at the rate of forty per hour. By this system a signature can be proven, a sketch or plan provided, a likeness sent, a draft with the genuine signature drawn. It is, at least, interesting to know that such processes are developing, however little they may be adapted to our hurried and enlarging correspondence. They can never destroy or supercede the simple processes now in use.

THE words of farewell promised in our last issue, are postponed for a few weeks, during which time we hope to reply fully to all communications on hand.

ANGLO-AMERICAN TELEGRAPH.—In anticipation of their meeting on the 16th day of February, the directors of the Anglo-American Telegraph Company have issued their report. It states that the total receipts for the past year accruing to the Anglo-American Telegraph Company, including a balance of £16,044 carried over from last account, amount to £274,731. The charges for repairing cables, with the ordinary working and other expenses and income tax, amount to £65,678, leaving a balance of £209,053. Out of this amount three interim dividends of 2 per cent. each, free from income tax, have already been paid, absorbing £96,856, and leaving a balance of £112,197. The directors, under the powers conferred upon them by the 164th section of the articles of association, before declaring the net profits, have set apart the sum of £50,000, for a renewal fund, and recommended that the balance, viz. :—£62,179, be appropriated to the payment of a further dividend of £3 3s. 4d. per cent. free of income tax, which, with the three interim dividends already paid, will be at the rate of 10 per cent. per annum, for the eleven months ending 31st December, 1871, leaving a balance of £9,156, to be carried forward to the next account.—*Mechanics' Magazine.*

THE JOURNAL.

We published a letter in our last issue referring very discriminatingly to the influence of the JOURNAL, and properly directing attention to the true method by which its usefulness can be assured. It rests much more largely in the hands of the operating force than in the Editor. A reflecting man, while pursuing his daily duties, is constantly meeting with some experience which is worthy of record, some difficulty for which some proper method suggests itself to overcome. He owes it to his fellows and his business to state them, so that his experience may have a record and a power. It seems scarcely proper that the Editor should adjudicate in such cases even were he at all times able to judge. He is only a learner with the rest. The man who toils at the operating table, or builds the lines, or hurries out in the storm to restore the injured structure, these are the men to write for the JOURNAL, and point out the remedies which experience suggests to them for any existent evil. The task becomes then that of the electrician. He has data furnished him of practical results, and the testimony and suggestions of experienced men. By his co-operation these may be formulated and worked into a system. Here is the path of true progress: Let every man who digs a hole for a telegraph pole, or erects one, or strings a wire, or manipulates a key, or watches a battery, suggest, how better to do all these, and the intelligence of the whole force will be stimulated and evoked. The personal portion of the article we receive gratefully. We have felt our chief work to be the infusion of fraternity and chivalrous companionship rather than of criticism. A new brain, with enlarged knowledge and with a sprightlier pen, will some day build on that basis an enlarged usefulness and a more substantial power.

ARGENTINE TELEGRAPHS.—The Inspector-General of Telegraphs in the Argentine Republic has notified that on the 16th of November he opened to the public service 400 miles of telegraph from Cordova to Tucuman, belonging to the Argentine National Government, and on the 1st of December 354 miles from Parana to Corrientes, being extensions to 638 miles already opened, making a total of nearly 1400 miles of telegraph, exclusive of provincial and railway telegraphs. On the 1st of January next the tariff on the national lines was to be reduced to a universal charge of 1s. The staff are now constructing the land line to the point where the country joins Brazil, to complete the communication to Rio.

NEW POSTAL TELEGRAPH CARD.—On and after Monday next postal telegraph cards, bearing a shilling stamp, will be issued, for the accommodation of those for whom it will be more convenient to deposit the card in the nearest pillar, letter, or other post-office letter-box, than to send a message to the nearest telegraph station. The telegraph cards will be taken from the boxes along with the other contents at the regular collecting periods, which are always specified on the table on or over the box; and on the arrival of a collection at the proper office, the telegraph cards will be at once picked out and handed over to the telegraph counter clerk, who will deal with them in the ordinary course, obliterating the stamp. No postage is charged, the shilling stamp covering that, and also franking the message on the card to the same privileges as are granted to messages handed in to offices in the ordinary way.

COUNTING GOVERNMENT MESSAGES.

FORT LEAVENWORTH, Ks, Jan. 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR—Allow me to suggest to you the following plan of reform in the manner of counting Government Telegrams, which I think if adopted, will be beneficial to both the Government and profession, in point of accuracy, viz.: let a given uniform number of words represent the address and signature, and transmit only the number of words that it is in the body leaving the designated number of words for the address and signature to be added to the check. I find that in the transmission of Government Telegrams through repeating Offices, operators are in the habit of counting such words as Fort Hays, U. S. Quartermaster, Headquarters, etc., etc., which generally occur in the address and signature of messages, one or two words as may be necessary to make the message count correct. The Company will be materially benefitted by the adoption of this plan, as operators will not have to hold open their key to count every message, but can write four or five words in a line, and count the message as they receive it. I find that from an average of one hundred telegrams sent and received at this Office, that allowing fifteen words for the address and signature of each telegram, would be as near justice to both the Government and Telegraph Company as can be arrived at. R.

A WISE OLD GENTLEMAN.

That Uncle Samuel could buy all the telegraph lines, reduce prices one-half and then make money, is quite apparent when one comes to read that while a private citizen or a corporation can ship goods from New York to Liverpool for from ten to thirty dollars per ton, the government pays nineteen hundred dollars per ton for its mails. The old gentleman is so much more shrewd than individuals that his profits on the postal telgeraph system would be enormous—perhaps almost pay the messenger boys.—*Detroit Free Press, Dec. 14th*, 1871.

THE POWER OF APPRECIATION.

CHARLESTON, S. C., Feb. 24th, 1872.

J. O. BRENNER, ESQ.,
Supt. 3d District, Augusta, Ga.

DEAR SIR:—During the fearful epidemic through which our city has recently passed, six of our number were stricken down, and but for the timely aid which was so promptly and liberally extended, it would doubtless have proved fatal to more than one of our number. As it was, they lacked for nothing that human aid and skill could supply. Those who escaped, through the goodness and mercy of a kind Providence, although but simply in discharge of a duty in performing somewhat more arduous tasks incidental upon the sickness of their co-laborers, have been made to feel that even so small an effort on their part has not been allowed to pass unnoticed, and their services have been fully appreciated.

Therefore we, the undersigned, employees of the Western Union Telegraph Co. at this place, desire respectfully to tender to you, and through you to the Company you so ably represent, our sincere and heartfelt thanks for your and their action toward us.

Our thanks are dictated by grateful hearts, and we pray their acceptance only as an earnest of our desire hereafter to prove, by works, how sincerely and truly we do appreciate such interest in our welfare.

Very respectfully,

(Signed) JOHN D. EASTERLIN,
GEORGE W. BELL,
S. W. CAPERS,
W. J. FLEMING,
D. M. DRISCOLL,
P. E. RYAN,
H. TOYS,
JNO. B. R. SPALDING,
JOS. FLYNN,
FRANK A. DRAKE.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
March 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since February 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

281 Avon, Ind.	246 Kingston, Ga., re opened.
158 Blue Rapids, Ks.	318 Monticello, Ill.
288 Burdick, Ind.	389 Morrison, Mo.
58 Carbondale, Pa., heretofore an Other Line office.	293 Madison, Ala.
	246 Marietta, Ga., re-opened.
379 Cuba, Mo.	28 No. Leominster, Mass.
* Chester, Conn.	446 Rosendale, Mo.
261 Corunna, Ind.	288 Ross, Ind.
* Coalburg, W. Va.	111 Smethport, Pa., heretofore an Other Line office.
447 DeSoto, Ks.	
356 Epworth, Iowa.	42 Somers' Point, N. J., re-opened.
298 Frankfort, Ill.	
24 Henniker, N. H.	230 Terry's Station, Mich.
231 Holland, O.	211 Vienna, Mich.
220 Highlands, Mich.	288 Whitings, Ind.
299 Knightsville, Ind.	

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.	*Leaves this Line.*
Chester, Conn.,	30 3	Hartford, Conn.
Coalburg, W. Va.,	50 4	Huntingdon, W. Va.

OFFICES CLOSED.

Port Clinton, Pa.; Sunny Side, Ind., and Westover, Md.

GENERAL INFORMATION.

All communications with the Montreal Telegraph Company concerning Montreal Junction "errors," "uncollects," &c., should be addressed "Montreal Telegraph Co., Montreal, Canada," and six cents postage must be pre-paid thereon. If stamped with only a three cent stamp, a charge of ten cents additional is made upon delivery.

Business (including money transfers) with Allegheny City, Pa., will hereafter be checked to Pittsburgh, Pa.

The name of the office heretofore known as Divide, Ks., has been changed to Colony, Ks.; Buchtell, Mich., to Loomis, Mich., and Evans Mills, Ala., to Evansville, Ala.

Centreville, Mich., in sq. 251, is in St. Josephs Co.; Centreville, Mich., on N. W. lines, is in Marquette Co.

Sandy Hill, N. Y., now in sq. 39, will hereafter be in sq. 45.

OFFICES HAVING "SPECIAL SHEET A."

Tariff to Harmsburg, Pa., will hereafter be same as Parkers Landing, Pa., and to Pawtucket, R. I., same as Providence, R. I.

ATLANTIC CABLE BUSINESS.

Pre-paid Replies.—Amounts deposited to pre-pay replies must be entered in account, and remitted as part of the tariff upon the original message; and must not, under any circumstances, be refunded without instructions from headquarters.

On and after March 1st, rates from London, England, to points named, will be as follows:

	Via Falmouth.	*Via Russia.*	*Ordinary Continental rate.*
Hong Kong,	$21 50	$21 50	$35 00
Shanghai,	21 50	21 50	41 25
Nagasaki,	26 50	21 50	46 25

The above rates are for twenty words or under; charge half rates for each additional ten or fraction of ten words.

Where the route beyond London is not indicated by the *sender of a message*, the "Ordinary continental rate" must be charged.

The words "via Falmouth" and "via Russia" are not charged for beyond London.

CUBA CABLE BUSINESS.

We are notified that the Cables from Kingston, Jamaica, to St. Thomas, are now completed, and open for business. The following rates must hereafter be collected:

From Kingston to	*10 words*	*additional words.*
Porto Rico and St. Thomas	$7 50	75c.

These rates must be added to present tariff to Kingston.

Messages for Windward Islands beyond St. Thomas, will be mailed at St. Thomas. In addition to tariff to St. Thomas, collect 25c. for postage.

WILLIAM ORTON, President.

THE WALL STREET TELEGRAPHIC SYSTEM.

[Correspondence of the Chicago Journal.]

I want to note here a special feature connected with finances in Wall street, and that is the perfection of its telegraph system. Less than five years ago a man invented and brought into the street, a telegraph system, that was at first viewed as a visionary affair, and no man, among all the brokers and bankers of Wall street, could be found to give it either favor or support. Finally, an erratic individual, so called at the time, was induced to invest $3,000 for a quarter interest in the new invention, and to give it a test. It did all the poor inventor claimed for it, and more, and the brokers in whose office it found a place for experiment, became interested in it, and a joint stock company, with a nominal capital of $250,000, was formed, and business entered upon. A central location was chosen for the general office of the company; wires were run out to a few offices, and to the stock and gold bonds, and a few instruments put in. The effect was wonderful. Instantaneous communication had been established so that prices could be telegraphed from the Board to the general office, and from there to the several brokers' offices, much quicker than the news could be carried by the messenger boys at that time universally employed. It soon became a necessity for a broker to have such quick communication with the stock and gold Boards, and the system has grown into such favor that now there are not less than one thousand offices, including every bank, broker's office, hotel, express company, dry goods and other establishments, furnished with them.

These thousand offices, as I have said, are connected with the general office of the Company, and this again with the Stock and Gold Boards. In each of these offices is a small instrument, placed upon a neat little bracket on the side wall, and covered by a glass globe. The instrument has two wheels, on one of which are the letters of the alphabet, on the other, simply the nine digits, and fractions of ⅛, ¼, ⅜, ½8 and so on. Resting on the top of each wheel is a small circular pad saturated with ink, beneath a strip of paper an inch wide, on a small drum, and which is forced through by a small ratchet work, and brought against the wheels. In the general office sit two men at a table; on it is a small instrument similar to that in use in the ordinary offices of ordinary telegraph companies, for the reception of messages. The operators in the Gold and Stock Boards send the prices of each particular stock as dealt in, giving number of shares and price, and as there is a constant deal, from 10 A. M. to five P. M., on a long list of stocks, at every shade of price the quotations are incessant. These he notes in a book made for that purpose. Before the other man seated at the table, are two large dials like the face of a clock; on one are letters to correspond with one of the wheels of the instrument for printing and describing; on the other are the numbers and fractions. He moves the hand upon the dial to G; the one thousand little wheels revolve to G. With the other hand he touches an instrument that throws the paper against the wheel, and G is printed in one thousand offices at once. He touches the dial on the other side and figures 109 appear in quick succession, and we have as the result the quotation of gold, 109. Thus is communicated in the space of one minute, the prices of half a dozen stocks from the Board to one thousand offices throughout the city, and printed in type any child may read. The banks are thus connected with each other, and with the Clearing House. It is more like the power of magic than the result of human ingenuity.

AGRICOLA.

IS IT FAIR.

CHICAGO, February 20th, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—I notice in Journal of recent date, a hint that the Executive Committee of the Telegraphers Life Insurance Bureau have accepted the offer of President Orton of Western Union Telegraph Company, that the Western Union Company would donate one hundred dollars to the heirs of each member dying while in the employ of the Western Union Company. But, if a member was in the employ of any other company, they would only receive one thousand dollars, instead of the dollar for each and every member in good standing, that is: there are now something near fourteen hundred members and probably not less than twelve hundred members will pay their assessments when due, so if a member in the employ of any company except the Western Union, is unfortunate enough to die, his heirs will be deprived of at least two hundred dollars, that actually belong to them. It is very liberal on the part of the Western Union Company to give their employees' heirs the hundred dollars, but when other members are cut off, it is very unjust to them in my opinion.

I claim that each and every member is entitled to the dollar for each and every other member, who pays his or her assessment. If the Western Union operators choose to accept Mr. Orton's offer, to take only one thousand dollars, providing the Western Union Company will give their heirs a bonus of one hundred dollars; that is all right, but I think it unfair to members, not in the employ of the Western Union Company, to compel them to take only one thousand dollars, when they are entitled to twelve hundred, and that too without the consent of the members themselves, or at least a majority of them, who are not in the employ of Western Union Company. I should like to hear from others through your columns, and see if I stand alone.

Respectfully yours, GEO. W. LEE.

ANSWER.—The question of limiting payments to one thousand dollars, is one that has nothing properly to do with the hundred dollar bonus, but should be looked at as a matter of policy merely. The membership is increasing rapidly, and the deaths will likely also increase. The question is, whether the members prefer to have a payment of a larger sum than one thousand dollars and pay an increase of assessments, or reserve the collections over one thousand dollars to meet some of these assessments and so limit practically their number. The bonus is a mere incident in connection with this question, and has properly nothing to do with it. The time indeed has not come to make it a question at all, for the heirs of Charles A. Kellogg only received $831, bonus and all, the number of delinquents is so great, as may be seen by the JOURNAL of February 1. Probably the matter will be reserved for decision at the annual meeting. One hundred and fifty new members have been added since January 1, and we have reason to hope that these new additions will bring to the associations increased steadiness and vitality.

MR. ROBERT B. HOOVER whom all will remember as the first to suggest a testimonial to Prof. Morse, and which eventuated in the statue in Central Park, has resigned his post as manager of the W. U. Teleg. Co., at Alleghany City, Pa., and accepts the position of Telegraph Superintendent, a Train Despatcher of the Marietta and Cleveland Railroad. It augurs much for the success of any enterprize when thoroughly worthy men, bearing an honest record of consistent fidelity and capacity are placed in executive position in connection therewith. That this has been done in the present case all who are acquainted with Mr. Hoover know. God bless him.

A FIREPROOF MAN.

About the year 1869, one Lionetto, a Spaniard, (writes a French chemist) astonished not only the ignorant, but chemists, and other men of science, in France, Germany, Italy and England, by the impunity with which he handled red hot iron and molten lead, drank boiling oil, and performed other feats equally miraculous. While he was at Naples, he attracted the notice of Professor Sementeni, who narrowly watched all his operations, and endeavored to discover his seerct. He observed, in the first place, that when Lionetto applied a piece of red hot iron to his hair, dense fumes immediately rose from it, and the same occurred when he touched his foot with the iron. He also saw him place a rod of iron nearly red hot between his teeth without burning himself, drink the third of a teaspoonful of boiling oil, and taking up molten lead with his fingers, place it on his tongue without apparent inconvenience. Sementeni's efforts, after performing several experiments upon himself, were finally crowned wtth success. He found, that by friction with sulphuric acid, diluted with water, the skin might be made insensible to the action of the heat of red hot iron; a solution of alum, evaporated until it became spongy, appeared to be more effectual in these frictions. After having rubbed the parts which were thus rendered in some degree insensible, with hard soap, he discovered, on the application of hot iron, that their insensibility was increased. He then determined on again rubbing the parts with soap, and after this, he found that the hot iron not only occasioned no pain, but that it actually did not burn the hair. Being thus far satisfied, the Professor applied hard soap to his tongue, until it became insensible to the heat of the iron; and having placed an ointment composed of soap mixed with a solution of alum upon it, boiling oil did not burn it; while the oil remained on the tongue a slight hissing was heard similar to that of hot iron when thrust into water; the oil soon cooled, and might then be swallowed without danger. Several scientific men have since, it is said, successfuly repeated the experiments of Professor Sementeni, but we would not recommend any but professionals to try the experiments.

WE are reluctantly compelled to omit assessment acknowledgements until next issue,

MARRIED.

COX—BOWERS.—At Bells, Tenn., by Rev. J. A. Carter, Mr. W. A. Cox, of W. U. office, Batesville, Miss., to Miss Sue Bowers.

BARNARD—LAWRENCE.—At Berea, O., Nov. 22, 1871, J. M. Barnard, of Berea, O., to Miss Eva Lawrence, of Olmstead Falls, O.

DAVIS—LANGE.—On the 17th inst., in Lawrence, Ks., by the Rev. F. M. Ellis, Jos A. Davis, Tel. Operator in the General Supt's Office of the L. L. & G. R. R., to Miss Maria T. Lange, all of Lawrence.

ENGLE—NCINTIRE.—Married Dec. 31st, 1871, by Rev. W. H. Pierce, A. C. Engle, operator, to Miss Lucinda McIntire, both of Dunkirk, Ind.

MEAD—BEEM.—At the residence of the bride's father, near Spencer, Ind., Dec. 28th, 1871, by Rev. G. F. Culmer, Mr. W. Stanley Mead, Manager W. U. Tel. Office, and Agent J. B. & W. Ry., Jamestown, Ind., to Miss Amma Beem.

BORN.

NYE.—At La Cross, Wis., February 12th, to J. M. Nye, a daughter.

LONG.—To W. C. Long, of W. U. night force, Chicago, Ill., January 2, a daughter—good sounder.

DIED.

ARNOTT.—At five o'clock, Monday morning, Feb. 19th, at the Union League Club, this city, F. George Arnott, after an illness of seven weeks of pneumonia, aged 20 years, 3 months and 19 days.

TURNER.—Died, Dec. 29th, 1871, Sophy M. Turner, beloved wife of D. N. Turner, Agent C. & N. W. R. R., Elgin, Ill., daughter of Dr. M. Prezinger, Euphemia, Preble Co., Ohio. age, 26 years and 7 months. For over two years Mrs. Turner was a patient sufferer from consumption. Just a few evenings before she died, when friends spoke to her of the beautiful christmas tree at church she said, "I soon shall see a far more beautiful sight, Jesus himself." She died calmly. A husband and little son mourn her loss.

16,000 MILES

OF

"JOHNSON'S" WIRE

USED BY THE

TELEGRAPHS OF THE UNITED STATES

DURING THE YEAR 1871.

This is sufficient refutation of all the intimations thrown out by the Manufacturers and Importers of other Wires, reflecting upon the acknowledged superiority of the Wire manufactured by

Messrs. RICHARD JOHNSON & NEPHEW,

MANCHESTER, ENGLAND.

Their Works are the Largest in the World.

The great advantage which they possess over other manufacturers is their patent process of drawing Wire in great lengths (averaging 1,200 feet).

All Telegraphers know that, in nine cases out of ten, breaks in Wire occur at joints, hence the less joints the fewer breaks.

Messrs. RICHARD JOHNSON & NEPHEW furnish three-fourths of all the Telegraph Wire used by the

ENGLISH GOVERNMENT.

This Wire is necessarily subject to the tests, etc., imposed by the English Post-office Department.

A large stock always on hand and for sale at the lowest market prices—both free and in bond.

TELEGRAPH LINES

OF ANY LENGTH FULLY EQUIPPED WITH

THE NONPAREIL TELEGRAPH APPARATUS.

(Patent applied for.)

This apparatus supplies a want which has long been felt, viz.: that of a SIMPLE and CHEAP

MORSE TELEGRAPHIC INSTRUMENT,

with all the necessary Batteries and other appurtenances in a CONVENIENT and COMPACT form.

By means of a switch, which is now placed on each instrument, they can be worked as desired, either as the open or the ordinary continuous, or closed circuits.

It is intended especially for the use of

STUDENTS, AMATEURS, AND OPERATORS,

but will be found to be equally well adapted for use on

PRIVATE TELEGRAPH LINES,

or Short Lines of any description, which are not over three or four miles in length.

A NEW FORM OF BATTERY

is employed, which is compact, efficient, and economical, and especially adapted to the purpose for which it was designed. Each instrument will be accompanied by a

BATTERY, CHEMICALS, INSULATED WIRE

for connections, together with an

ILLUSTRATED BOOK OF INSTRUCTIONS,

which in itself forms a complete elementary treatise upon the ART OF TELEGRAPHY.

PRICES:

Single Instrument, complete, with Batteries, etc.....$8 00
Two Instruments, " " " " 15 00

Sent by Express on receipt of price.

Remittances may be made by Post Office Order, Registered Letter, or Draft payable to our order. Persons ordering Instruments will please write plainly, giving Post Office, County, and State, with instructions for shipment. Address,

F. L. POPE & CO.,
P. O. Box 6010. 80 Broadway, (Room 51,) New York.

AMERICAN FIRE ALARM

AND

POLICE TELEGRAPH.

GAMEWELL & CO., PROPRIETORS,

NO. 104 CENTRE STREET, NEW YORK.

J. W. STOVER,
General Agent and Superintendent.

L. B. FIRMAN, Chicago, Ill.,
General Agent for the West and North West.

J. R. DOWELL, Richmond, Va.,
Special Agent for Virginia and North Carolina.

J. A. BRENNER, Augusta, Ga.,
Special Agent for Georgia and South Carolina.

L. M. MONROE, New Canaan, Conn.,
Special Agent for New England.

This system of Fire Alarm and Police Telegraph, with a Central office, or upon the

AUTOMATIC PLAN,

is now in operation in the following cities, to which reference is made for evidence of its great SUPERIORITY, VALUE and UNIFORM reliability:

Albany, N. Y.,	New Orleans, La.,
Alleghany, Pa.,	New Haven, Conn.,
Boston, Mass.,	Newark, N. J.,
Buffalo, N. Y.,	Omaha, Neb.,
Baltimore, Md.,	Philadelphia, Pa.,
Chicago, Ill.,	Pittsburg, Pa.,
Cincinnati, Ohio,	Portland, Me.,
Columbus, Ohio,	Peoria, Ill.,
Cambridge, Mass.,	Providence, R. I.,
Charlestown, Mass.,	Quebec, L. C.,
Covington, Ky.,	Rochester, N. Y.,
Detroit, Mich.,	Richmond, Va.,
Dayton, Ohio,	ndianapolis, Ind.,
Elizabeth, N. J.,	t. Louis, Mo.,
Fall River, Mass.,	St. John, N. B.,
Fitchburg, Mass.,	Springfield, Mass.,
Hartford, Conn.,	San Francisco, Cal.,
Jersey City, N. J.,	Savannah, Ga.,
Louisville, Ky.,	Syracuse, N. Y.,
Lawrence, Mass.,	Troy, N. Y.,
Mobile, Ala.,	Toledo, Ohio,
Montreal, Canada,	Toronto, Canada,
Milwaukee, Wis.,	Washington, D. C.,
New York City,	Worcester, Mass.,
Lynn, Mass.,	New Bedford, Mass.,
Lowell, Mass.,	Bridgeport, Conn.

The distinctive features of these systems of

FIRE ALARM AND POLICE TELEGRAPHS,

ARE,

First—The AUTOMATIC SIGNAL BOXES, the simple electro-mechanism of which enables any one—even a child—to give an *instantaneous, general,* and *definite* alarm of fire.

Second—The AUTOMATIC REPEATER, through which the apparatus may be distributed in a combination of circuits, and the entire system successfully worked without the constant personal attention of either operators or watchmen.

Third—The ELECTRO-MECHANICAL BELL STRIKERS, adapted to produce the full tone of the largest church or tower bells.

Fourth—The ELECTRO-MECHANICAL GONG STRIKER, for hose and engine houses, by means of which the location of the fire is instantaneously communicated to the members of each fire company.

These features combined form the

ONLY PERFECT, COMPLETE, AND RELIABLE SYSTEM

OF

FIRE ALARM TELEGRAPH IN THE WORLD.

Messrs. GAMEWELL & CO. are the owners of the original *FARMER AND CHANNING PATENTS,* one of the most important of which has just been extended for seven years. During the past seventeen years they have spared no expense or effort to secure improvements, and the systems are now covered by

MORE THAN TWENTY PATENTS.

The introduction and operation of the

AUTOMATIC SYSTEM

involves so little expense, compared to the benefit which it confers, that even small communities can profitably adopt and maintain it.

The co-operation of TELEGRAPHERS in securing its introduction into their localities is cordially invited, and their efforts will be duly appreciated and compensated.

Any information desired in regard to the above system will be cheerfully and promptly furnished upon application at the office.

A pamphlet setting forth more fully its advantages and superiority, has been printed, and will be supplied to Municipal Authorities and others interested in Fire Alarm and Police Telegraphy upon application as above.

To the Editor of the Journal of the Telegraph:

I am reminded of the days when I was young in years, and telegraphing by a young lady who is "Morseing" it, in great profusion, under my instruction. Standing beside her the other evening, while she was making her first enquiry for "No. 21," I noticed her key was open, and inquired why she didn't close it; "Oh!" said she, "I want to wait and see what he is going to say!" She is desirous to become a sound operator. In answer to her question "How long it would take," I thoughtlessly said three months or so, and, with that gallantry which characterizes (?) the profession in their intercourse with "beginners" I consented to give her a lesson semi-daily. At the close of the first one, (30 minutes duration) she solemnly informed me that she thought what I had been calling (H B) sounded some like a "C"! with an imagination so lively, will not three months witness perfection? Another young lady — evidently new to the business, while in office recently, noticed a bunch of W. U. T. Envelopes in close proximity to one of the relays, and modestly enquired if I "usually received them that way"? They have some enlightened operators on the new line from St. J— to S—n. One of them gave me a call not long since personally, I was favorably impressed, I supposed he was a Supt., at least, till he astonished me by placing his hand on a key, and asking me if I worked "all them three wires" with it? One word for the benefit of any perplexed brother and I am done. I scold sometimes—I did when Capt. K—— brought me a message some one had handed him from train, I couldn't read it and I said so. Why, said he, "do as I do when I am copying, make the letters just as nigh like his as you can and let it go at that!" EXNTITE.

MECHANICAL TELEGRAPH INSTRUMENT

PATENTED MAY 31st, 1870.

For Students, Colleges, &c. No battery required. An ordinary key and sounder is placed upon a proper base. The sounder is moved by a lever under the base, connected with the key, making a perfect instrument for those wishing to learn the Art of Telegraphy. An expert could not tell, without examining it, that the instrument was not worked by a battery.

It should be introduced into every school and family where there are those who wish to learn the Art.

Hundreds of persons throughout the country desire to become expert Telegraphists, and are constantly seeking permission to practice in the various telegraph offices.

This instrument is an outgrowth of this pressing demand. The Inventor is himself a practical operator, now in active service. Operators and others wishing to teach or learn the Art, will be delighted with this instrument.

It can be placed anywhere, as it does not occupy a space more than six inches square.

Its cost is but $7, and there is no expense whatever to keep it constantly in working order.

We will send a copy of SMITH'S MANUAL, free of charge, with each instrument, to individuals or clubs. The instructions in this Manual are particularly adapted to those who wish to learn by sound.

Special and liberal terms to manufacturers.

Remittances can be made by certified draft on New York, Cleveland, or Pittsburgh, money by express, charges paid, post office order, or registered letter at our risk.

Parties ordering instruments, from points except well-known cities, will please give the name of county and State.

Price, $7. Silver Plated, Extra Finish, $10.

Address, D. W. PUTT & CO., Wellsville, O.

D. W. PUTT,
P. BRUNER,
W. G. BROWNSON.

These instruments can also be procured at the same price from L. G. Tillotson & Co., New York; Bliss, Tillotson & Co., Chicago, Ill.; Chas. Williams, Jr., Boston, Mass.; M. A. Buell, Cleveland, O.

WIRE IN BOND.

For the accommodation of the SOUTH AMERICAN, CUBAN and MEXICAN TRADE, we shall hereafter keep a stock of the Celebrated

"JOHNSON" WIRE,

both plain and Galvanized, in Bond, ready for shipment from New York.

PRICES AS FOLLOWS:

No. 9, Plain Annealed.....4¼ cts. Gold.
No. 9, Galvanized.....5¼ "
No. 8, Plain Annealed.....4¼ "
No. 8, Galvanized..... 5 "

This Brand of Wire is the best in the world, and has been adopted exclusively by the Western Union and many other Telegraph Companies.

We also continue to import this Wire for use in this country, notwithstanding the high rate of duty imposed by Congress in the interest of the monopolists. Any amount of it can be seen at our store at all times. The import duty on wire is now two cents per lb. gold, and 15 per cent. *ad valorem*.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 8. NEW YORK, MARCH 15, 1872. WHOLE NO. 105.

THE INVENTOR OF THE GROVE BATTERY.

MR. GROVE is the son of a Welsh gentleman of property, and was born in Glamorganshire, in 1811. He was educated at Brasenose College, Oxford, and took his M. A. degree in 1838. He studied law in London for two years, and was called to the bar of Lincoln's Inn in 1835. Being compelled by ill health to surrender the more active duties of his profession, he, fortunately for science, devoted his brilliant intellect to the investigation of physical phenomena, especially those of electricity. One of the first productions of his researches was his invention in 1839, of the voltaic battery which has given him a world-wide fame. Subsequently, in 1840, he received the chair of experimental philosophy at the London Institution, and continued to occupy it for seven years; and it was in the fulfilment of his duties as a lecturer that his courageous originality and penetrating diagnosis were shown in the assertion of the correlation and mutual convertibility of the various species of force. This announcement, one of the most brilliant lights over the field of nature which has ever illuminated the path of the investigator, and one of the greatest discoveries which has been made since Newton promulgated the laws of gravitation, is now universally accepted as indisputable truth; and Mr. Grove's experiments have substantiated the fact that no force whatever can be evolved except at the expense of some other force. The new doctrine gave the word at which many other scientists commenced their labors, and proofs of the truth and importance of the Doctrine of the Correlation of Forces are coming before us daily. Mr. Grove further developed his views in another lecture, published in 1846. Among his many valuable and important discoveries are the gas voltaic battery, the striæ in the electrical discharge, the electricity of flame, the voltaic etching of daguerreotypes, the electro-chemical polarity of gases, new combinations of aplanatic object glasses of telescopes, and the monecular impressions by heat and electricity.

Although Mr. Grove's weak health formerly prevented him from following the arduous career of a popular advocate, as a lawyer he has achieved a high reputation for learning and forensic ability, and he has just received a fitting recognition to his talents by his elevation to the judical bench. To a philosopher of Mr. Grove's renown, the public honors and wealth are of little importance, and indeed, his acceptance of the judicial ermine will cause him to forego a lucrative practice, and take the moderate income of $25,000 a year. But the ease and dignity of the new position will enable the eminent recipient to prosecute further his investigations, and we have no reason to doubt that the world of knowledge and science will be greatly benefitted thereby.—*Scien. Am.*

THE Golden City and South Platte Railway and Telegraph Company has been organized in Golden City, Colorado, under a grant of the right of way to build a narrow-gauge road along the base of the mountains, and connect with the Denver and Rio Grande road at Littleton, ten miles southeast.

A PRACTICAL SUGGESTION ABOUT LABOR.

CLEVELAND, March 9, 1872.

To the Editor of the Journal of the Telegraph:

I have been observing the steady increase of the half rate, or red business, since the Company first commenced its operation, and am pretty clearly convinced that the manner in which it is now handled is not only an encroachment upon full rate business, but an unnecessary tax upon day operators. In large repeating offices day operators are obliged to perform a certain amount of hard labor during the early portion of the night, in order that half rates may be accommodated in common with full rates. This is wrong. I believe it was understood when the half rate system first commenced, that it should follow the *completion* of *all other business*, and which, probably, was done for a short time. But now much of the greater portion of our night commercial business is caused by the steady increase of half rates, not only with large offices, but with smaller ones, and not less than three-fourths of it is done between six and nine o'clock P. M.

This course necessitates the labor of a certain number of the day force every night, who report for duty at 7.30 and 8.00 A. M., consequently putting in about twelve hours' work against an average of seven hours for the regular night operators.

There is an easy remedy for this evil, which can be applied in very large repeating office, without detriment to half rates, and giving full rates their proper attention and promptness. Small offices, which close about 9 P. M., should be allowed to send and receive their half rates during the hours prior to closing of the same night, which would not be enough increase to interfere with full rates, or cause much increase in force. It would not make much difference if half rates, originating at smaller offices, were left over until the following morning, as they would be delivered about as soon as most all smaller offices are in direct communication with a large repeating office.

Large repeating offices should *not* be allowed to start a half rate before ten o'clock at least, and an hour later would serve the purpose better. By that hour the full rates are out of the way, and the regular night force is complete, as in most all large offices an extra operator or more comes on duty at about eleven o'clock. The half rates can thus be handled leisurely during the balance of the night by all large offices, and be forwarded to smaller ones early enough in the morning for all practicable purposes.

This arrangement would, of course, have to become general throughout the whole extent of the Company's lines to be effective, and work harmoniously. It would not do for New York to hold his half rates until 11 P. M. and let Chicago send his at any time after 6 P. M. This plan seems feasible, and discriminates not only in favor of full rates against half rates, which is certainly just, as no person will argue but that full rates have preference in all cases and at all times, but in a certain degree dispenses with the extra service of day operators at night. In writing up this article, I do not wish to be understood as being partial to one class of operators more than another, my only object being to facilitate the full and half-rate business of the Company, in doing which it places the two branches of business in their proper spheres, and makes an immense amount of labor now performed by day operators unnecessary without doing injustice to regular night operators. It is to be hoped that these suggestions will receive proper consideration. "S."

A SUPERINTENDENT'S OPINION.

TOLEDO, March 8th, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—The President having invited an expression of views as to the probable effect and working of the new tariff of State rates, I beg leave to give in my testimony on the subject so far as my experience in the service since 1855 will bear me out. I do not expect to surprise you with any new discovery, or extraordinary and brilliant ideas in relation to the tariff system, but merely corroborate the opinions and statements of a host of others, from whom, no doubt, you will hear on this same subject.

What is the effect to increase or lower the rates? It is plain that the public generally pay but little attention to slight changes in tariff, only where you have competition. With the bulk of the business, especially between important points, it is more a question of time than money. A route that can give the safest and quickest transportation and maintain itself, will eventually take most of the business. If you meet competition successfully, you must carry as cheap and as prompt as the opposition.

What are the evils of the present tariff? Most any system of tariff you may adopt will be understood and successfully carried out by managers of large offices, but it is a notorious fact that nine-tenths of the Western Union offices do not obey instructions given from time to time relating to the old tariff. When you consider the manner in which the Western Union business is handled on most lines throughout the country, and the numerous changes occurring at offices, you can readily see that it is impossible to first educate and then get managers to carry out your instructions. A large proportion of the check errors arise from this cause, together with imperfections in the rates when first issued. I am satisfied that this evil is magnifying, and results in great loss to the company.

It is evident that the new State rates will in the end increase the earnings; for comparison shows that between points where the bulk of the business is now done, the old rates will be maintained, but between distant non-competiting points, with some exceptions, the new rates are higher and will go into effect, and I cannot see that the reduction in local rates will overbalance, or even equal the increase in earnings on business between distant points. As the country develops the business between distant points will, of course, rapidly increase. The sooner a uni-

Digitized by Google

form tariff is adopted the better, and I know of no plan that will work so smoothly, less liable to create errors, and so easily comprehended by the offices and the public generally, as the new plan proposed, but I should suggest reducing the new rates twenty per cent. and then cut loose entirely from the old tariff, so far as the rates between Western Union offices are concerned. You will be obliged, of course, to maintain special rates between competing points, and preserve the old record of other line rates. The use of the *asterisks* will, I fear, work mischief.

Very truly yours,

G. A. Beach, Sup't.

PRAYER BY TELEGRAPH.

"Vidi," the distinguished New York correspondent, says:

The prayer meeting in Fulton street is a sensitive barometer of the religious world of the United States. The attendance has increased quite fifty per cent. since the first of February, and the exercises are marked by uncommon zest. Daily instances of awakening conversion occur among persons present. Reports of new revivals and conversions are sent in daily from churches in different parts of the country from which had previously come requests for prayer. A number of new daily union prayer meetings send greetings, and desire prayer for their permanence. I looked in the other day at 12:55 o'clock (the hour for closing), as a gentlemon rose, saying: I, too, am from the West; and I want to tell you of something I lately witnessed there that has thrilled my heart. During the late convention of Young Men's Christian Associations in Zanesville, Ohio, daily dispatches were passing by telepraph between associations in different parts of the country and the convention.

An operator at Zanesville, who received and transmitted the messages, was invited to the devotional meeting, and carelessly consented to go in. It was but a few minutes before he was seized with the conviction that he was a sinner, and rose to ask prayer for himself. Before that meeting closed he rose again, and with great joy declared his faith in the Savior, saying that he felt as certain that God had forgiven his sins as that he stood there. Shortly after, a delegate, who had been to Zanesville, returned to Cincinnati and told the story. An operator in the Cincinnati office heard of it. He said to himself, "That's rather a sensational story, and I don't believe it." During an idle hour in the office it occurred to him to test the story. So he called Zanesville. Zanesville answered, and he asked the question: "Was an operator converted in the Christian Association Convention in your place the other day?" "Yes," was the answer, "and I am the man. Are you a Christian?" "No." "Then come with me to Christ. I want to pray with you. Will you kneel down now and pray for yourself while I pray for you?" "All right." Then, continued the speaker, they closed that telegraphic circuit, and opened one with heaven! God answered. The soul of that operator was converted, and the very next evening he went into the meeting of the Young Men's Christian Association, told his story and confessed his faith. Names, dates and references were given to vouch for this strange story, and as the speaker concluded another jumped up in a remote corner by the door and said: "I want to say one word!" The leader said "No," and was giving out the closing verse, but the stranger persisted, and said: "I can confirm every word of the story just told, for I was present myself at the telegraphic prayer meeting."

A TARIFF SUGGESTION.

To the Editor of the Journal of the Telegraph:

That a map be struck off, with merely names, States and towns, and tariff to be computed by measurement, say so much to the inch or fraction of same, using ordinary rule, or an instrument could be made for the purpose, the rate decreasing in proportion to the distance, which could be specified on the instrument. New offices could be located and inserted by stating (through the Journal) the distance by measurement on an air line between two offices already located. The map need not necessarily be large or costly—would hardly cost more than the book we have. Any dispute as to tariff could be readily decided by each Superintendent, as he could make the test and learn the rates between any two points given, which cannot well be done by the present.

Manager in Texas.

MINNESOTA.

St. Paul, Minn., Jan. 29, 1872.

To the Editor of the Journal of the Telegraph:

Dear Sir:—We seldom see an article in the Journal from our beautiful State, and begin to think it time it was brought to notice. We certainly deserve a small space occasionally in one of your interesting sheets.

This State is rapidly advancing in wealth and industry, and particularly in Telegraphs and Railroads. They now extend beyond the Red River of the North far into Dakota, are rapidly approaching the Missouri, and will soon penetrate into the last remaining hunting grounds of poor "Lo."

The flash of the electric telegraph, through the indomitable energy of the North Western Telegraph Co. also reaches into the North British possessions, and connects Fort Garry with their brethren in Canada.

St. Paul is destined to be the great centre of the telegraph and railroad systems of the North-West. We already have eight railroads centering here. Others are projected and under construction, eleven Telegraph lines diverging from here in all directions, and others to be built next Summer.

Our seasons are magnificent and wonderfully healing to the invalid in many cases. Occasionally hyperborian breaths on us a little cooler than is agreeable, but it is healthy, vigorous and bracing. The thermometer does not often go below 45; in such cases you want to keep up the steam to keep your pumps from freezing, if you get far away from the stove.

A great many persons East, have an idea our city is a one horse village, and that the people are principally half breeds and Indians. Those benighted beings had better come out if they want to see as substantial a city of nearly thirty thousand inhabitants as there is in the country, with as sharp business men, and as large business houses as are found any where. Another erroneous impression prevails that we are snowed in and frozen up, from October to June, we have just enough snow to make good sleighing, and our Spring is earlier than in many Eastern States.

The opposition line still lives, but judging from reports, it is rapidly declining up this way.

It is like a snake, the tail will wiggle a long time after the head is cut off. When the Duluth line was taken from them they lost their head.

Occasional.

The construction of the South Australian overland telegraph is proceeding rapidly and the line is now open eleven hundred miles from Adelaide.

OLD AND NEW CABLES.

The primitive cables do not appear to have been constructed with much attempt to proportion to any extent either their mechanical strength to the depth of water in which the cables were to be laid, effects of currents, &c., or the degree of insulation to the peculiar requirements of the line; nor, indeed, could the latter be affected, as is in the earlier attemps at cable manufacture and laying, the tests applied were of the crudest description. The fact that a message could be sent through the cable was considered a sufficient guarantee of its electrical soundness. It was due to these causes that such a large number of the earlier cables either never worked at all, or became inoperative in a very short time. The first attempt of any importance, at a refinement in cable manufacture, was made in the first Atlantic cable. Here, however, it was carried to too great an extent, and sufficient allowance was not made for the occurrence of any accident which might put an undue strain on the cable, such as would be caused by stormy weather, during the laying; neither were any steps taken to protect the cable from corrosion; so that on any attempt to raise it for repair, the rusted wire would give way, and the cable could not be raised to the surface of the sea. These difficulties have, to a great extent, been overcome, so that with the present system of paying out machinery, which works with almost clock work smoothness and accuracy, and the accurate and searching system of electrical tests, the manufacture and laying of a cable is of secondary interest, and excites but little public attention.

The cables now generally adopted are of two kinds. The first of these are very similar to those first constructed. They consist primarily, of "the core," which is constructed with various weights per mile of copper, and insulating material, according to the length and required working capacity of the line. The core is first served with a coating of hemp, tanned, to preserve it as far as possible from decay; this hemp acts as a padding for galvanized iron wires, which are laid on spirally around it. The whole is then coated with a second serving of hemp, which is covered with a silico-bituminous compound, laid on hot. This being pressed on by grooved rollers, gives the cable a smooth, round surface. In the second type of cable, the iron wires, before being laid on, are each of them, served separately with the coating of hemp, the outer serving being omitted. It is the latter type of cable which was used for the 1865 and 1866 Atlantic lines. In both types, the first serving is laid on wet, so that any fault which might occur in the insulation during manufacture, can immediately be detected and traced. The object of coating the iron wires with hemp, is to prevent any broken ends from projecting and catching in the paying out gear, an accident which would be certain to cause the fracture of the cable. Altogether, therefore, this last improvement is one of the most important that has been effected in the manufacture of cables. The idea of light cables; that is to say, cables with only a hemp or other light material sheathing, does not seem to have many advocates among the leading manufacturers and engineers; and it is doubtful, whether the public could ever be got to risk their capital in them. For, although undoubtedly cheaper in the manufacture, they are liable to turn out costly adventures. And is more doubtful since the present system of metal sheathing has been found to answer so well.—*Mechanic's Magazine.*

Mr. Cyrus W. Field sailed from Liverpool for New York on the 9th instant on the Cunard steamer Cuba.

Digitized by Google

HUMORS OF THE TELEGRAPH.

We cannot withhold the following: A man under full steam is something to admire. This letter is in answer to a "caution" by Supt. Miller. It is very loud. Read it and stand from under. Now, Mr. McSweeney, fire away. Mr. Miller will meanwhile order his coffin.

To the Editor of the Journal of the Telegraph:

J. N. MILLER, *Superintendent, &c.*,

Chillicothe, Ohio.

My Dear Sir:—In the JOURNAL OF THE TELEGRAPH of the 15th inst., you stigmatized me as an "unprincipled telegrapher, unworthy of confidence."

You say I am "going the rounds practising impositions upon companies where I am unknown,—that I have recommendation from good parties, but of an old date." We will dissect this sentence now, and see how the account stands between us. Immediately upon my return last fall from Albany to Cincinnati, I applied to you for employment in the capacity of night operator, and stated that it *should* be at a county seat containing not less than five thousand inhabitants. You replied, stating that you had such a vacancy—sent me a pass, and I reached Chillicothe on the next subsequent train. I called at your gloomy sanctum, introduced myself, and submitted my letters for your approval. You expressed great satisfaction with my letters and my *physique*, and inquired why it was that a person of my acknowledged abilities should seek so insignificant a situation as I asked for. I told you I had been reading law for some two years; that I had just completed by legal education at Albany, and that owing to the depleted condition of my treasury, I would be obliged to return to telegraphing for a few months until I could accumulate enough money to rent and furnish an office, and "hang out my gold lettered sign." I also said I was not a first-class operator, hence my anxiety to secure a situation of comparative obscurity. You mentioned Athens as being the office then vacant; you represented it as being a place of some four or five thousand inhabitants, who were energetic and public spirited; as possessing good hotel accommodations; and as being an exact prototype of its Grecian namesake in her palmiest days. I left Chillicothe for "classic" Athens, on Monday morning, and upon reaching there, I discovered the telegraph office to be located in an abandoned cow shed, and a whiskey shop filled with blear-eyed, bloated and frenzied Athenians but a few paces off. This was rather an unpleasant introduction, but I concluded to waive those disagreeable features, provided the other representations you made proved to be true.

After scaling a lofty hill and reconnoitering for information, I learned that the place contained nearly fifteen hundred inhabitants, that owing to its great age it was rapidly crumbling into ruins, and that I could not secure board for less than two dollars per day, unless I slept on the "hurricane deck," and on the same mattress with a filthy and intemperate cordwainer. Discovering myself to be a victim of your premeditated duplicity, I concluded to retaliate by requesting you to assume the indebtedness I thus contracted, and return to Cincinnati at once; to this you consented, and because I have not recompensed you for your deception, I am denounced as being "unprincipled and unworthy of confidence." Saint Matthew tells us that if we are wronged by a friend, we must go to that friend and acquaint him of the injury privately; but you, an unhallowed pile of smoldering ashes, not only ignores the admonition of the venerable Apostle, but publicly denounce me for not performing an act that would be derogatory to law and repulsive to morals. Renegade, slave, coward, liar, slanderer, murderer of the Queen's English, hackwriter and policy spy, the one small service you could do me was to villify me, and such as you are may all my villifiers be.

Again, you say, "his sojourn with this company was one night received, and fearfully bulled one commercial messenger, struck out next day." It was Daniel O'Connel's exclusive prerogative to hurl a vigorous young brood of thoughts before the public without a tatter to cover their nudity; but it remains for you, a tottering monument of adnascent imbecility, to outstrip my illustrious countryman in assassinating her Majesty's English, and dressing your uncouth productions in habiliments fresh from the looms of your own meretricious imagination. I have struggled long and manfully against the twin vicissitudes of poverty and adversity, and have met many a scowl in my day,—I have traveled a good deal during the past six months, hoping I would eventually succeed in securing a situation favorable for the prosecution of my legal labors, but amid all my discouragements and during all my travels, I challenge you *or any one else* to point to a single spot contaminated by my footprints. You are one of these shivering imbeciles, who, like Goethe's scoffing fiend,

"Bleibt stets von Schlag,
Und ist so wunderlich als wie am ersten tago."

Another one of your choice innuendos, and I will have completed the unpleasant task of your infamy imperishable. You say "his *modus operandi* is to work for a few days, get possession of money enough to compensate services, and suddenly depart, leaving all debts unpaid." You will soon be called into court sir, to establish the truth of this accusation; until then I leave you to your own meditations, with the admonition, however, that if I again have occasion to meet you through the press, I will raise excrescences such as windgalls, spavins and fistula upon your emaciated carcass, that all the horse doctors in christendom cannot heal. But I must conclude, lest some cosmopolitan humanitarian should prosecute me for cruelty to animals.

Respectfully, &c.,

T. McSWEENEY.

BLOOMINGTON, ILL., March 1st, 1872.

Aint that Dutch terrible! Mr. Miller is not a member of the Insurance Association.

ELECTRO-MAGNETIC WATCH-CLOCK.

We all remember the remark of Coleridge in reference to the river Rhine: "The Rhine," said he, "washes Cologne; but what power shall wash the Rhine?" So it is easy to hire watchmen; but whom shall we get to watch them, and see that they do their duty? Fortunately, science has not left us without assistance in this matter; and tell-tale clocks, and other mechanical contrivances, enable us to tell, without a possibility of mistake, whether or not a watchman has done his duty. The Hamblet clock may be placed in the office, or in a separate building at a distance from the premises to be guarded. A system of wires radiates from the clock to all the buildings and premises, and to the points which it is desirable for the watchman to visit in his tour of duty. At each point, or station, the watchman inserts and turns a key, or simply touches a knob, which causes the electric current to pass and do its work upon the magnet at the clock, and produces a penciled record on a paper dial at the exact instant when the key is turned. The watchman in this manner, passing around from station to station, successively, makes telegraphically his own record of duty done, showing the time of each visit to each station, as well as the time occupied between the stations; and of course the whole time taken up in making the entire round, and also in going all the rounds; and, if all the stations have been visited or have been neglected, the facts will be shown upon the dial. In fact, the superintendent can read in the morning the exact part of the premises at which the watchman was at any minute of his required tour of duty during the night. The paper record-dials are changed daily, and may be filed and kept as a permanent record of the watch duty, interesting to insurers; being a time-record made by the watchman himself, and which he can make in no way except by visiting the stations in regular order. The clock can be constructed to combine the recording instruments of a number of watchmen in the same case; they have been set up for eight and ten watchmen in one clock. The clock has a sixteen-inch time-dial, with full-length seconds pendulum, dead-beat escapement, and maintaining power. The case is seven feet four inches high, twenty-four inches wide, with recording instruments for two watchmen. It is the invention of Mr. J. Hamblet, Jr., who is associated with the firm of Messrs. E. Howard & Co., of Boston, Mass., and is very ingenious and perfectly reliable.

PATENTS.

TELEGRAPH PRINTING APPARATUS.—Henry Van Hoevenbergh, of New York city.—This invention has for its object to produce a simple and convenient mechanism for reversing the motion of the type wheel of a telegraph printing instrument. It is intended for use more particularly on an instrument for telegraphing stock quotations, etc., where it is desirable to have a reversible type wheel, and thereby avoid frequent necessity of making almost complete revolutions to reach types that may be brought to action by a short back movement. The invention consists in a new revolving gear actuated by a separate current through an independent wire, and in a new double pawl mechanism for actuating the type wheel shaft. The invention also consists in the application to the latter of a stop whereby its motion is arrested, if and as long as it is not in concert with the other instruments that are operated simultaneously by the same keys.

ELECTRO-MAGNETIC ENGINE.—Claude Victor Gaume, Williamsburg, N. Y.—This invention has for its object to furnish an improved electro-magnetic engine, simple in construction and effective and reliable in operation, being so constructed as to be free from the "pull back" or retardation which is a great objection to such engines as usually constructed. The armatures consist of a central bar, attached at its center to the face of a wheel, and having cross heads formed upon them about midway between their centers and end, the cross heads having short bars formed upon their ends parallel with the central bar, and the ends of which project to equal distances upon the outer and inner sides of said cross heads. Armatures thus constructed are claimed to be free from the retardation or "pull back" which was the great difficulty to be overcome in making electro-magnetic engines practical as a motive power.

ELECTRO-MAGNETIC ENGINE.—Henry S. Daggett, of Lafayette, Ind.—This invention relates to a new arrangement of stationery magnets and vibrating conductors, and to a new combination of the same with a sliding piston rod and vibrating link movement, whereby a complete electric engine is produced, imparting a reciprocating motion to the piston and other suitable action to the mechanism connected therewith. Magnets arranged in rows and connected with wires and pendant chains, a piston provided with a swivel lever which moves under the chains and thereby produces successive connections with the several rows of magnets, stops affixed to the frame for swinging the lever at the end of every stroke, and thereby reversing the motion of the engine, and an electric engine consisting of frame rack, magnets, wires, chains, piston, lever, and stops, all combined to operate as described, are the features upon which a patent has been obtained.

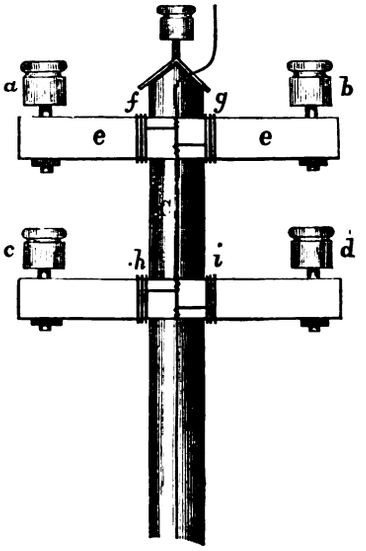
FAMILIAR TELEGRAPH TALK.



A correspondent asks in reference to what we said about the use of glass knobs for interrupting the main wire in front of office, "Will common glass insulators answer the purpose?"

There is a certain sense in which many things may be used to accomplish the same purpose, and an ordinary glass insulator, by punching out the head, and putting one wire through it and another across it, will, no doubt "answer." There used to be made, however, a knob of very pure glass, for this very purpose, which, with a troublesome eye like ours, we would greatly prefer. It had a thickness of 1¾ inches, full round edges of equal diameter, and a centre groove for one of the wires. The other passed through a central transverse hole. Its only advantage lay in the purity and smoothness of the glass, and in its neatness, which latter quality, we think, should never be despised.

With this digression, we add another. The discharge of lightning is, as all know, accomplished by having the office wires pass, on the "cut out," a knob of brass connected with the earth. There is no doubt that this plan is effective to a degree, convenient, and, generally, safe; yet, we have always entertained the opinion, that if a carefully planted ground wire could be applied to a pole a short distance from the office, one on either side, it would be a great advantage. Of course, it would require care. What good result is ever accomplished without it? A small box could easily be made in connection with an insulator, into which the ground wire could enter, and, being fixed to a neighboring pole, by shutting off the maximum of a lightning charge, would give the interior shunt less to do, and thus more perfectly preserve the magnet from injury, or the plan of the annexed cut might, if the wire was isolated from the pole, be adapted.

The plan adopted in England for carrying off the inductive currents, of which Mr. Varley gave us the accompanying cut and which is now being employed by Superintendent Tubs and others, to protect our prairie structures from destruction from lightning, would, of course, be effective in the matter we propose. It would save the occasional burning of office connections, and the setting on fire of office windows, of which we have sometimes heard, and would preserve the integrity of many an injured magnet core. We think if we were manager of a way office we would avail of every means of keeping our office in prime order. But we counsel every one against carrying out such an idea as last named on his own hook. We are merely taking an operator's privilege of saying things as they occur to us, and these may form the subject of a conversation between an operator and his superintendent, which may lead to knowledge of a purer and better kind.

We think we were the first to devise a mode of discharging lightning from an office, and for which we received a very flattering notice from the Hon. Amos Kendall, in the Washington *Globe*, sometime in 1846, and the presentation of a silver medal by the Philadelphia Franklin Institute. It was done by using a magnet of coarse wire, similar to a sounder, between the line and the relay. The line wire was connected to the arm of the armature; and the wire which led to the relay was connected to a post on which the end of the armature arm opposite the magnet was made to rest by a spring which detained it. The post back of the magnet had a ground connection. This magnet was adjusted so that the ordinary current did not affect it. When, however, a lightning current passed, the magnet drew down the arm and discharged the dangerous current at the ground post. This was thought quite an achievement in these early days, and we were correspondingly elated by our success. It looked very handsome on the table, and we gave it all possible honor. But not long after, when a brave youth stuck a piece of paper round the gas pipe and made the main wire pass round it, thus discharging all Jupiter's thunderbolts in this very vulgar way, we put our medal away, and took our magnet home never to use it again. It was a short-lived glory that, but was good while it lasted. Not long after this, Gen. Stager conceived the idea that a pointed permanent magnet, brought near the main wire, would be a sensitive arrester of these sky currents, but the gas pipe prevailed until regular arresters of different forms were made part of the office machinery. The history of these, their many forms, plates locked together with a separating paper, wire brushes in proximity, platina points shooting at each other, charcoal beds, might be curious, but too long. It was one of the points on which genius exuded freely, and of which we should not complain having set the example. We think we should have passed the silver medal to the gas pipe man, but we were human and didn't. The come down was too great. It was the sublime upset by the ridiculous; yet the ridiculous won.

The casualties by lightning entering offices have been rare, yet were regarded at one time as alarming. The first occurred at Greensburg, Pa., in 1848, when the window sash caught fire, and caused much apprehension. At Zanesville, O., a few years later, all the wires were fused as in a furnace. A few similar cases have occurred, but all apprehension has long ceased, and the wires are looked upon with a friendly eye as protectors, although one good farmer's wife insisted that her best cow was dried up because, while being milked one day, she stood against a telegraph post. In England, no doubt, that cow would have been examined by some electric expert and reported upon, but it remains an open question to-day, "was that cow dried up by leaning against that pole and why?"

One day in 1846, while engaged in building the lines in Pennsylvania, as we sat by the side of the Columbia Railroad with our men, eating our frugal noon meal of milk and bread, a fine bull calf came strolling around, looking at us, and apparently not at all displeased with our looks or mode of living. It was a warm summer day, and we had had sundry atmospheric shocks from the wire as we strung it on the poles. Near where we sat, the new wire we were erecting hung from a pole to within four or five feet of the ground. To this, the enquiring calf betook itself, and, as many a man has done, touched it with its tongue, when, with a loud and disgusted baa, and with a tail like a disgusted ramrod lifted up on high, the young bull leaped the nearest fence, quite satisfied with his electric experience, yet in no way anxious for more. The way he went over the rail fence was almost æronautic, and decidedly bully. From this juvenile bull may be learned how dangerous it is to kiss the wires in summer time, and to what relays are subject when due care is not taken to give them protection of the most perfect kind. These flashes are hammer strokes hardening magnet coils.

CHECK ERRORS.

To the Editor of the Journal of the Telegraph:

DEAR SIR: Please give your decision. If I receive a message from a distant office signed by a transient party say to forward his trunk, requiring an answer. I send answer to collect, but check is changed in transmission by a repeating office and message is received paid. In due time comes the error sheet. The transient party has gone. Now, who is to pay, or whose error is it? The Company will have the money; I am told to get the other office to collect, and in case he can't collect I am to forward the amount. Can this be right? Yours truly,

MANAGER X.

When an error of the kind indicated is made, there being no record to prove the contrary, the presumption is against the sender. Hence the directions given. The appeal then must be to the Superintendent, who will do justice in the case, and permit a charge of "refunded," when made clear to him. These, however, are questions of management and routine, which are left to the discretion of Superintendents, and the mode of deciding which must often bring into use arbitrary rules and exceptionally incorrect decisions, so far as due performance of duty is concerned.

In the case you name it seems that the message must have had its payment provided for as an answer for a transient party, before the original was forwarded as required by the rules. This might have led to a detection of the error made against you. Yet we cannot see how the check department could act in any other way than it has.

HOLLY SPRINGS, MISS., March 5th, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR: Please decide following controversy between this office and Jackson, Miss. I say that according to Rule Nine, Third Paragraph, United States Hotel, United States Attorney, United States Marshal, are each counted three words. Jackson says the first is three, but the last two are only two words each. Please let us hear your opinion through the JOURNAL. Very truly yours, HOLLY SPRINGS, MISS.

ANSWER.—Jackson is right. "United States" according to Rule Nine, First Paragraph, is one word when used to designate the nation or officer thereof. "United States Hotel" is distinctly given in the Book of Rules as three words, as United States there has no national significance, has no national reference.

TRAIN ORDERS.

SOUTHERN KANSAS, March 1, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR: In No. 103 of the JOURNAL I notice an article, written by "A.," of Jacksonville, Ill., in regard to train orders. He thinks the following order is correct, which *is*, as far as it goes. He has only partially corrected "Green Flag." Both trains can be embraced in one order, as A. claims, viz: "To Conductors and Engineers Nos. 1 and 2. Trains Nos. 1 and 2 will meet at A." To make the order complete in the above it should be. "To Conductors and Engineers Nos. 1 and 2: Trains Nos. 1 and 2 will meet *and pass* at A." In A.'s order it does not mention pass, although common sense teaches us that they should and will pass, but *meet and pass* should be in an order to make it complete.

Yours fraternally, M.

EXPERIENCE is a good teacher, and when a man working at his trade, invents anything by which to facilitate or improve his labor it has the assurance of a practical value. We have just been called upon by Mr. David Emminger, a practical telegraph repairer from Harrisburg, Pa., where we first commenced our telegraphic career, with a glass insulator of what strikes us as an improved form, and with a novel addition to it. The insulator is 4½ inches long, diameter 1¼ inches at top and 3 inches at the edge of the bowl or water drip. The peculiarity of the form is, that the sides are perfectly straight from the top to the water drip, by which the rain runs readily off and perfectly cleanses the glass. This was proven by an insulator taken from the line which on its upper slope was clean, but on its lower and perpendicular side was coated with the smoke deposit from passing cars.

The chief feature of the insulator however is that about an inch and a half from the top four triangular glass lugs are formed on the cylinder, with a slot in each for the reception of the wire. On two of these the main wire rests, touching only the edges of the two lugs, and the binding wire the other two. Thus the bearing of the wire on the glass is reduced as in the Chester insulator to a minimum, but without the use of a metallic yoke as in the Chester.

AMONG the changes taking place in the Executive force of the Central Division of the Western Union Telegraph Company, we notice the retirement of D. H. Ogden, Superintendent of the lines on the Sioux City and Pacific Railroad, and the appointment of E. D. Titus to the post thus made vacant. Mr. Ogden has been a good and efficient officer and enters pursuits of greater promise of remuneration. Mr. Titus, we are assured, is a fit successor, a careful and capable and energetic man. The telegraphic interests of the West are daily assuming vaster proportions, and men of prime executive ability are needed for its development and care. The present condition of the Western management reflects the highest credit on Mr. J. J. S. Wilson, Superintendent at Chicago, on whom it largely depends, under General Stager's eye, for its vigor and character.

REDS.

To the Editor of the Journal of the Telegraph:

Please give your decision upon following case:

A man, or firm, buying and selling considerable grain, seed, &c., by telegraph, comes into telegraph office at seven o'clock P. M., asks if there is a telegram there for him, is answered in the affirmative, and has a red message from New York handed to him, quoting late markets. Has he the right to answer the same by red message that night. If not, and he refuses to reply by full rate, can the W. U. Co. be held responsible for any loss that he may sustain thereby?

Again, after receiving his red message from New York, has he the right to buy or sell articles of the same kind at some other point, by using red blanks that night? If he has not the privilege of replying to a red message, with a red the same night, or cannot use red in buying or selling on the same, what authority then have we for delivering the same to him, on the date of receipt of the same, even if called for at the counter?

ANSWER.—You started wrong. The red message should not have been delivered until morning. That answers all the rest.

RAILROAD ITEMS.

Mansfield, Coldwater & Lake Michigan.

The entire portion of this line in Ohio, except about twenty miles, is graded, and two weeks of good weather will suffice to complete the work. On the Michigan end, eighty miles are graded and tied with only eight to grade, and early in the season the entire line will be in operation, giving unbroken rail communication with Muskegon.

Canada, Michigan & Chicago.

The Company proposes to build a railroad from St. Clair to Lansing, to be operated in connection with the Peninsular Railroad.

Louisville & Cincinnati.

A charter has been granted for and work has been commenced on a narrow-gauge railroad from Louisville up the Ohio to Westport, and efforts are making to secure a charter which will complete the line along the river to Covington and Cincinnati.

Lake Erie & Louisville.

This Company, it is reported, has closed a contract for the construction and equipment of its line from its present southern terminus at Findlay, Ohio, southwest through Lima and St. Mary's, Ohio, and Union, Ind., to Cambridge, Ind., 1,500 tons of iron to be delivered May 1, or as soon as navigation opens; an equal amount June 1, and 2,000 tons July 1, which will complete the road to St. Mary's, Ohio, 52 miles, and the remainder for the whole line as fast as it can be used. There is now 37 miles of the road in operation, from Fremont to Findlay. The completed line would be almost an air line from Sandusky to Louisville.

East Line & Red River.

This Texas company, recently organized in Jefferson, is preparing to construct a railroad from Jefferson northwest to the Red River near Sherman, Texas, a distance of about 150 miles.

THE Dominion Telegraph Company, of Canada, report its ownership of one thousand one hundred and seventy-six miles of line, bearing two thousand two hundred and sixty-five miles of wire. It reports also eighty-three offices opened in the Province of Ontario. Issued capital, $270,000. A dividend at the rate of five per cent. on paid-up stock was paid in December, on the business of the eighteen months preceding. The lines of the People's Telegraph Company in the province of Quebec have been purchased, adding three hundred and thirty-four miles of poles and six hundred and sixty eight miles of wire to the property of the Company. The United States connections of the D. T. Co. are with the Atlantic and Pacific Telegraph Company, and are based on an agreement for twenty years from April last.

THE *Evening Post* announces the introduction of a new stock and gold printer, the invention of Mr. Robert H. Gallaher. There is a curious sentence in the rather curious article which announces this last scientific wonder, which is peculiar. It says: "In the opinion of many, the Callahan instrument falls short of what is needed, as it does not keep up with the fluctuations of the stock market during exciting times." We think this must have been written by the same pen which announced the remarkable heating of the wires on "Black Friday." The peculiarity of the new printer seems to be in that, instead of an alphabet wheel, by which announcements are compared, the names of certain stocks are set on the type wheel, so as to be struck off at once when quoted. This is a device simply to get round the existing system, and while it obtains a slight advantage apparently, loses the power of general telegraphic employment.

NEW YORK, MARCH 15, 1872.

SPRING DUTIES.

As Spring opens, of course the active out-door telegraph work will be resumed with new vigor, and, we trust, under the stimulus of a higher knowledge of the necessities of the business. We refer now specially to that part of the labor of the lines, which fall upon the men engaged in repairs.

We shall, for example, soon have upon us the usual Spring rains, as well as the usual plethora of business which attends the opening of navigation, and the commencement of Spring trade. The lines are now working splendidly, because the weather is clear, sharp, and there is no demand upon the insulation. But the moment rain falls, then, every broken glass, every bare bracket, every string hanging across the wires, reveal their capacity to interfere with the office work. This is, therefore, the time when every repairer should be sent out with the special duty of supplying every broken glass, no matter how slightly diminished by breakage, with a new one, and removing every obstruction of every kind. It was only a few days ago, we took up our old duty for a few minutes as we were hurried along in a lightning train to look up at the lines. Generally, everything was in perfect order. But, just as we neared a small wooding station, we found the upper wire entirely without insulation on two poles, and the glasses badly broken on five more. Of course that wire will be more or less useless when the rain comes. We believe that it would pay managers of offices to inspect personally the wires along the routes on either side of them, and they owe it to themselves to insist on a complete insulation of that part of the structure which affects their office work. We say this without any desire to reflect on the repairing force.

One great error is a most common one. A repairer imagines that if a glass is merely fractured, so that a part of the bowl is gone, while the part around the pin remains perfect, that no change is necessary. Thus it is that thousands of broken lipped glasses remain upon the poles in all directions. Now this is a fault which should be ended. No broken glass should be allowed to remain a day after its discovery, and no labor is more profitable than that which preserves the insulation complete. Are we presumptuous in saying all this? Are you all ready for the rain?

A NEW BLADE OF GRASS.

The saying is trite that he who makes two blades of grass to grow instead of one, is a public benefactor. We suppose this is true only if the grass be good, and grass be desirable. If all flesh is grass, and the good book says it is, we think that one blade of that kind is sometimes as much as this world can stand, and some blades flourish entirely too long for the happiness of the world and the rest of mankind. We have no one specially in mind at this writing, so no one need to feel bad about it. When, however, it does really happen that a man of creative talent increases the richness of the verdure of the fields, and man and beast obtain thereby a new chance to live and a new help to labor, there is not a bird above nor a fish below but should, each in its own way, sing a psalm of thanksgiving. And so should we.

One of the wildest propositions, to our thinking, used to be the idea of using a wire for the double purpose of, simultaneously, transmitting and receiving messages; in other words, of writing both ways, on the same wire, at the same time. We had been assured of its use on the Continent, and non-experts—that is, people generally—were only troubled about the way the switch could be managed, so as to allow the messages to pass each other, they regarding a wire much as a single-track railroad. But we could not, and we say it honestly, see how such a thing could be. We fear that we gave too little credit to the possibilities of human invention then, just as we are likely chargeable now with giving too much. On the continent, however, by more than one process, yet with limited success, has this apparently paradoxical feat been long since accomplished. It has not been so successful, however, as to have come into any considerable employment, or attracted special attention.

By certain improvements, however, in the combination of the transmitting apparatus, Mr. J. B. Stearns, of Boston, has succeeded, in so marked a measure, in accomplishing this very valuable result, that its introduction as a feature of American telegraphy seems, to say the least, probable. It has been tested on circuits of different lengths, and, we believe, through repeaters, to distant points, with promising success. It is thus made apparently possible to double the capacity of every wire. Here is an element of profound worth. It is of simple application. It involves no expensive machinery. It requires no unusual talent to work it. The Western Union Telegraph Co. are giving it a fair trial. We shall be glad if it prove an entire success on the long circuits which our far separated, yet actively connected, commercial centres require. And we shall be glad to crown the quiet and unassuming man, who belies his name by the gentleness of his manners, as the benefactor who has given us a veritable "new blade of grass."

THE French Atlantic Cable Company have purchased the contract for a new Atlantic cable announced to have been made by Messrs. Bischoffheim and Goldsmith with the Telegraph Construction and Maintenance Company, and will prepare for a speedy laying of a fourth cable between England and New York direct, to be worked in the interest of the existing companies.

PERSONAL.

We are doubtful of the propriety of publishing any of the many kind letters of which we have lately been the recipient. They can, however, hurt none but the one to whom they are addressed, and that only by the possible charge of indelicacy to which their publication may make him liable. The two following letters are too valuable to keep to ourselves. We wish all to enjoy the pleasure they have afforded us. In Mr. Orton's letter will be found a tone of tenderness such as seldom comes from the Executive of a company to a retiring subordinate, and which we fear in our case is not wholly deserved. We read it in tears and rejoice in its possession. It cannot fail, we think, to attach to him, more closely than ever before, the whole staff of men, who, over this whole continent, serve under his administration. To him, we may be permitted now to say, we have been drawn from the first by an instinctive devotion, which deserves no name which expresses less than personal love. The pang we feel in sundering ourselves from the service of the telegraph, which, God knows, is strong enough, is not half so keen as that which separates us from him. We need not say that we are only too happy to continue to serve the JOURNAL until May, and even thereafter in any way in which we can usefully supply a word to its columns.

FROM PRESIDENT ORTON.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH CO.,
NEW YORK, March 1, 1872.

James D. Reid, Esq.:

MY DEAR SIR: * * * * * *

I have never forgotten the pleasant intercourse of the few months succeeding our connection with the United States Company. I was an ardent pupil and you a cheerful and patient teacher. I have not forgotten your prophecy, made long before indications were visible to me, even of the first step, that, some day, all the telegraph lines on the Continent would be consolidated, and that I would be at the head of their control. Your prophecy has been fully realized within the period of which you speak. I should be ungrateful, indeed, to feel otherwise than kindly towards one who, knowing me but little, predicted for me so brilliant a success, so honorable a career. To achieve that success has involved labor and study to an extent that left me no leisure for social amenities, nor for other than the briefest personal intercourse. The experience in the telegraph which you have been a quarter of a century in acquiring, I have endeavored to concentrate within five years, and at the same time to discharge the new duties which have been imposed upon me. If I have ever appeared to neglect you, it was because my thoughts were intent upon a business which has had all my time, all my abilities, and almost my life. Your apparent respect—more, your evident friendship—has always been grateful to me, and it grieves me to think that I may have been so unfortunate as to have failed to give evidence that these sentiments were heartily and entirely reciprocated. I hope never to climb so high as to get beyond the reach of the friendly hands and kindly voices which have aided and cheered me on.

I designed to have stated to you some time ago, what was true then, and is truer now: *You have done well.* The JOURNAL has more than realized any expectations I dared entertain of its usefulness when established. And now I fully comprehend your need of rest. I realize also the advantages which a new sphere of duty may offer you. If you can secure both of these in the field you propose to enter, I shall not regret the loss which the telegraph will sustain. It would, however, oblige me much if you would continue to look after the JOURNAL until May first.

Although the paths we have pursued, respectively, during the last six years, seem about to diverge, perhaps never again to come together, I shall feel always a warm interest in whatever concerns you.

It should be some gratification to carry with you into the new field of effort on which you propose to enter the consciousness that the labors you have bestowed upon the telegraph have borne, and will continue to bear, abundant fruit. Your life has been a continual exhortation to industry, temperance, and frugality, and thousands have been made better by the influence of your example.

That God will bless you, my friend, and give you at the last "that peace which passeth all understanding," and which is the complete and only compensation for a faithful life, is my hope and prayer.

Sincerely, your friend,

WILLIAM ORTON.

We add the following welcome note from Professor Morse. We are not aware of any special kindness we have shown to him. We joined with the thousands of our comrades in doing him a deserved honor. Yet we confess the power of a personal attachment to him and the heating of our blood when his rights have been questioned. So we are very grateful for his recognition of us. We have worked in the trenches long and lovingly. The recognition of such men is honor enough under which to close the campaign.

FROM PROFESSOR MORSE.

5 West 22d Street, Feb. 28, 1872.

My Dear Friend Reid: I perceive by your last Journal of the Telegraph that you are about to retire from the editor's chair. I truly felt saddened at this announcement, for in my long and intimate acquaintance with you I have ever found you a conscientious as well as an intelligent man, and one who deserves the respect of all who value honor and integrity. Your personal kindness to me demands some recognition, and I ask your acceptance, therefore, of the accompanying articles as a slight token of my personal esteem. I can present them to you now, on your retirement from your position, without incurring the suspicion of other motives than those I have professed, which are those of the highest personal respect, and the sincerest wish that your future career may be one of profit and honor. Sincerely, your old friend,

Samuel F. B. Morse.

Accompanying this note were several articles of table silver service, which we highly prize.

TRANSFER SERVICE.

Newcastle, Pa. office has been transferred from E. P. Wright's district to C. O. Rowe's district.

Pittsburgh, Pa. has been added to the list of "*offices specially authorized.*" I. O. Hendrickson, Agent.

Executive Office,
Western Union Telegraph Company,
New York, March 16th, 1872.

Executive Order No. 138.

Hereafter all complaints of error or delay in the transmission of cable messages, and applications for refunding on the same, should be accompanied by the original copy of the message as delivered in Great Britain or on the Continent. WILLIAM ORTON, President.

Pope's Modern Practice of the Telegraph, enlarged edition, we state again, in answer to several enquiries, is a most excellent and carefully prepared text-book, and such as must commend itself to all telegraph students. Mr. Van Nostrand, Publisher, has left copies in our hands for prompt mailing, and on receipt of the published price, two dollars, it will be mailed, post-paid.

The Western Union Telegraph Company has purchased the large property situated on the northwest corner of Dey street and Broadway, to be the site of a new and enormous headquarters. An attempt was made, in the first instance, to buy the Astor House for this purpose, in order to bring the headquarters of telegraphy on this Continent as close as possible to the post office. This attempt, however, was a failure. The Company then made a bid for the estate situated on Dey street. This property extends between fifty and sixty feet on Broadway, and runs to a depth of one hundred and fifty feet on Dey street. It was originally purchased by Dr. Evans, the American dentist at the late Court of France, for $480,000, in behalf of Louis Napoleon. The ex-Emperor sold it to the Western Union Company, through Dr. Evans, for $850,000, thus netting the nice little margin of $370,000 for himself. The property will be assumed by the first of May, after which all the buildings at present there located will be torn down to make room for an enormous and elegant structure, which will be the headquarters of the Company —*N. Y. Times.*

This does not look much like selling out to the Government.

SPECIAL STOCKHOLDERS' MEETING.

Executive Office,
Western Union Telegraph Co.,
145 Broadway, New York, March 9th, 1872.

Notice is hereby given, that in accordance with Article I of the By-Laws of the Western Union Telegraph Company, and on the request in writing of a majority of its Directors, a Special Meeting of the Stockholders of said Company is hereby called, to be held at the Executive Office of the Company, in the City of New York, on Wednesday, April 3d, 1872, at 1 o'clock P. M., for the purpose of authorizing the issue of Bonds of the Company to an amount not exceeding the sum of Fifteen Hundred Thousand Dollars, secured by mortgage upon the real estate of the Company on the corner of Dey Street and Broadway, in the City of New York, in order to provide funds for the payment of the remaining instalments of the purchase money of said real estate, and for the erection of a suitable building thereon.

The Transfer Books will be closed for this purpose at the close of business on the 23d inst., and will be opened on the morning of April 4th.

Stockholders may vote at said meeting personally or by proxy, and in pursuance of the usual custom a proxy is enclosed herewith. If not able to be present, please sign and return to the Secretary, who will put on and cancel the required revenue stamp.

WILLIAM ORTON, President.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

Executive Office,
Western Union Telegraph Company,
145 Broadway, New York,
March 15, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since March 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the Journal *as possible.*

NEW OFFICES.

GENERAL INFORMATION.

The following is a revised list of offices on the Marietta and Cincinnati telegraph line, with "Tariff for Other Lines" from Cincinnati, Chillicothe and Marietta, O.

Route of business same as heretofore.

Barlow, O.	85	6	Cincinnati, O.
	70	5	Chillicothe, O.
	45	3	Marietta, O.
Belpre, O.	75	5	Cincinnati, O.
	65	4	Chillicothe, O.
	35	2	Marietta, O.
Big Run, O.	75	5	Cincinnati, O.
	55	4	Chillicothe, O.
	40	3	Marietta, O.
Blanchester, O.	45	3	Cincinnati, O.
	50	3	Chillicothe, O.
	75	5	Marietta, O.
Frankfort, O.	60	4	Cincinnati, O.
	35	2	Chillicothe, O.
	65	4	Marietta, O.
Greenfield, O.	55	4	Cincinnati, O.
	40	3	Chillicothe, O.
	65	4	Marietta, O.
Hamden, O.	70	5	Cincinnati, O.
	40	3	Chillicothe, O.
	55	4	Marietta, O.
Hillsboro, O.	80	6	Cincinnati, O.
	85	6	Chillicothe, O.
	110	8	Marietta, O.
Jackson, O.	70	5	Cincinnati, O.
	45	3	Chillicothe, O.
	60	4	Marietta, O.
Leesburgh, O.	55	4	Cincinnati, O.
	40	3	Chillicothe, O.
	70	5	Marietta, O.
Londonderry, O.	65	4	Cincinnati, O.
	35	2	Chillicothe, O.
	60	4	Marietta, O.
Lynchburg, O.	80	6	Cincinnati, O.
	85	6	Chillicothe, O.
	110	8	Marietta, O.
Mineral City, O.	70	5	Cincinnati, O.
	50	3	Chillicothe, O.
	50	3	Marietta, O.
Martinsville, O.	50	3	Cincinnati, O.
	45	3	Chillicothe, O.
	70	5	Marietta, O.
Madisonville, O.	35	2	Cincinnati, O.
	60	4	Chillicothe, O.
	75	5	Marietta, O.
New England, O.	75	5	Cincinnati, O.
	55	4	Chillicothe, O.
	40	3	Marietta, O.
New Vienna, O.	50	3	Cincinnati, O.
	45	3	Chillicothe, O.
	70	5	Marietta, O.
Petrea, O.	70	5	Cincinnati, O.
	45	3	Chillicothe, O.
	60	4	Marietta, O.
Scott's Landing, O.	75	5	Cincinnati, O.
	60	4	Chillicothe, O.
	30	2	Marietta, O.
Vincents, O.	75	5	Cincinnati, O.
	60	4	Chillicothe, O.
	35	2	Marietta, O.
Zaleski, O.	70	5	Cincinnati, O.
	45	3	Chillicothe, O.
	50	3	Marietta, O.

The P. O. address of Hicks Ferry, Pa., is Bell Bond, Luzerne Co., Pa.; of Oakland, Pa., Mountain Home, Monroe Co., and of Liberty, N. Y., Cohocton, Steuben Co., N. Y.

The name of the office heretofore known as Petersburg, Clarion Co., Pa., has been changed to St. Petersburg, Clarion Co., Pa., and that of Mantua, N. J., has been changed to Wenona, N. J.

Business for Wenona, N. J., should be checked to Woodbury, N. J.

Hereafter business for Camden, S. C., will be sent and checked to Columbia, S. C., instead of Kingsville, S. C., as heretofore.

The office at Tionesta, Pa., will hereafter be checked as an Other Line Office, "tariff for other lines" 25 and 2 from Oil City, Pa., check Oil City.

Business for West Killingly, Conn., should be sent and checked to Danielsonville, Conn.

The square for Osage, Mo., will hereafter be 389 instead of 388.

Tariff for Other Lines from Little Rock to Arkadelphia, Ark., will hereafter be 100 and 7.

Business for Mason City, Iowa, will be checked as on Northwestern lines. See Journal Supplement of February 1, 1872.

OFFICES HAVING "SPECIAL SHEET A,"

will hereafter use "special rate" to New York city in computing tariff to Hunters Point, L. I., also check Mohawk, N. Y., same as "Special rate" to Ilion, N. Y., and Carbondale, Pa., same as Special rate to Scranton, Pa.

CUBA CABLE BUSINESS.

We are notified that the Cables to the Windward Islands are now completed and open for business. Following are rates in gold to all points beyond Havana:

To	*Offices in U. S. East of the Mississippi River, including St. Louis, Mo.* 10 Words.	*Extra Words.*	*Offices in Nova Scotia and New Brunswick.* 10 Words.	*Extra Words.*	*Offices West of Mississippi River, except St. Louis, Mo.* 10 Words.	*Extra Words.*
Santiago de Cuba,	6.25	.53	7.25	.63	9.00	.90
Kingston,	7.50	.66	8.50	.76	10.25	1.03
Porto Rico,	11.25	1.03	12.25	1.13	14.00	1.40
St. Thomas,	11.63	1.07	12.63	1.17	14.38	1.44

TELEGRAPHERS' MUTUAL LIFE INSURANCE.

TWO DEATHS.

We are sorry to have to record the death of two members of the Association since our last issue.

The first is that of George Henry Patriquin, one of the staff of the New York, Newfoundland and London Telegraph Co., at Plaister Cove, who died at Tatamagouche on the morning of February 29th. Mr. Patriquin was seized with typhoid in December last, and after a struggle of six weeks, his lungs became so much affected that he sank in rapid consumption. He was twenty-four years old, joined the Western Union Telegraph Co. in the fall of 1867, at Plaister Cove, and has served in that office since the transfer until the illness which terminated in his death. He was a consistent member of the Temperance Association there, and was beloved by all who knew him. Such is the brief record sent us by Mr. Scanlan his chief.

This death calls for

ASSESSMENT NO. 26.

The second death is that of Naylor L. Brown, long an operator in the New Orleans office, who died at Athens, Tenn., at the home of his mother, March 3d, 1872. His mother is represented as in needy circumstances. We have as yet no further particulars.

This death calls for

ASSESSMENT NO. 27.

As the avails of Assessment No. 26 belong to the heirs of Mr. Brown, they will perceive that no settlement can be made until that assessment is collected, the only money on hand being a few advance payments for which credit is duly given.

As the Association enlarges, it will be found a convenience as well as perhaps a necessity to have some one who will act as the agent of a district to whom money can be sent. Perhaps the superintendents, many of whom are members, would be willing to make some arrangement by which this could be easily and unlaboriously done. The remittance of money has been a great bar to membership, and some here resigned because of its uncertainty.

A NEW TREASURER.

As our prospective release from our present duties has made it necessary to resign the Treasurership of the Association, to take effect April 1st, the members are called upon to nominate some one for that office.

At a meeting of the Executive Committee, held March 11th, it was

Resolved, That a general meeting of the Association be called to meet at 145 Broadway, on the 21st instant, at 5:30 P. M., to take action in regard to the resignation of Mr. J. D. Reid as Treasurer, and the election of a successor.

We have performed the duties of Treasurer now for four and a half years, and, although it has brought much labor and absorption of time, yet we have great cause for gratitude that we have had a part in so beneficent a work. The Association has been a blessing to many a family and lighted up many a dark heart. Now we would like to be succeeded by the very best man who can be found, and we merely whisper to our friends that we think they cannot do better than vote for Mr. A. S. Brown, the worthy and trustworthy manager of the operating department in New York. We presume votes will be permitted by mail, and it is very important that a good man be chosen. The Association is enlarging, nearly two hundred having joined since January first, and it will require, of course, much wisdom to properly direct its development.

Of course various questions arise in connection with the Association from time to time which lead to discussion, but none so far to disturb its harmony. For example: A member allows his membership to go by default of payment After a couple of years he is an applicant for membership again. His certificate of health is all right, but, on the books nine assessments have been made since he dropt his membership, and he wants to avoid these by coming in as a new member. This the Executive cannot do. A member can be restored only by paying up all past dues. Such is the present rule. Time may make it necessary to modify it, but at present there is no escaping it, and none can complain of its injustice.

About a year ago, ten young men in a distant State applied for membership. They were accepted. Soon afterwards Assessment No. 21 was declared. The Secretary, under a mistaken idea that these parties were not liable for that assessment, notified them to that effect. No. 21 therefore stands a blank on the Treasurer's books, and the parties claim exemption because of the official notice. Now, in morals, nothing false is binding. It is equally true in common sense. Suppose the Secretary had notified these parties that they were liable for No. 20. Would they have paid it because officially notified? The argument wont bear stating. The executive board cannot waive payment, for they have no right so to do. Nothing can close the blank in the book but payment. The most careful of men will make an error. Every member is liable for every assessment ordered after the date of his certificate.

TELEGRAPHER'S MUTUAL LIFE INSURANCE ASSOCIATION.

Payments received on Assessment No. 25, occasioned by death of Charles A. Kellogg, in Rochester, N. Y., February 3, 1872.

HUMBOLDT, TENN., Feb. 26, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR: The announcement of your intended withdrawal from the editorial charge of the JOURNAL, which you have conducted so ably, reminds me of a neglected duty, that of remitting you the inclosed P. O. order for subscription past due. All who are identified with the telegraph, many of whom have not had the pleasure of a personal acquaintance, have learned through the JOURNAL to honor and love you, and your leaving our ranks will be universally regretted.

Trusting that you will survive many happy, prosperous years, I bid you good-bye.

Yours truly, E. HOWARD.

EXETER, N. H., Feb'y 23, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR: I wish to add my voice in "furthering" the suggestion of D. N. T. in last JOURNAL. Would be willing to pay two dollars per year for a revised and corrected quarterly tariff work. The amount of uncertainty it would save would be worth twice the sum.

Respectfully, X.

BORN.

WHEELER.—At Collinsville, Conn., March 12th, to Perlie A. Wheeler, Operator, a nine-pound son.

MILER.—At Williamsburgh, N. Y., February 11th, to Thos. M. Miler, a son.

THE LOVERS.

IN DIFFERENT MOODS AND TENSES.

Sally Salter, she was a young teacher who taught,
And her friend, Charley Church, was a preacher who praught;
Although his enemies called him a screecher who scraught.

His heart, when he saw her, kept sinking, and sunk,
And his eye, meeting hers, kept winking, and wunk;
While she, in her turn, fell to thinking, and thunk.

He hastened to woo her, and sweetly he wooed,
For his love grew until a mountain it grewed;
And what he was longing to do then he doed.

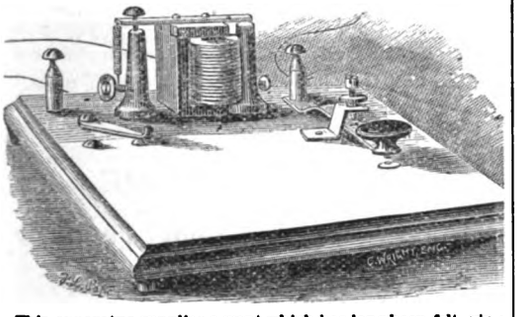
In secret he wanted to speak, and he spoke,
To seek with his lips what his heart long had soke;
So he managed to let the truth leak, and it loke.

He asked her to ride to the church, and they rode;
They so sweetly did glide, that the both said they glode,
And they came to the place to be tied, and were tode.

Then homeward, he said, let us drive, and they drove,
And as soon as they wished to arrive, they arrove;
For whatever he couldn't contrive she controve.

The kiss he was dying to steal, then he stole;
At the feet where he wanted to kneel there he knole,
And he said, "I feel better than ever I fole."

So they to each other kept clinging, and clung
While Time his swift current was winging and wung;
And this was the thing he was bringing, and brung.



The man Sally wanted to catch, and had caught—
That she wanted from others to snatch, and had snaught—
Was the one that she now liked to scratch, and she scraught.

And Charley's warm love began freezing, and froze,
While he took to teazing, and cruelly tose
The girl he had wished to be squeezing and squoze.

"Wretch!" he cried, when she threatened to leave him and left,
"How could you deceive me as you have deceft?"
And she answered; "I promised to cleave, and I've cleft"

THE NONPAREIL TELEGRAPH APPARATUS.

(Patent applied for.)

This apparatus supplies a want which has long been felt, viz.: that of a SIMPLE and CHEAP

MORSE TELEGRAPHIC INSTRUMENT,

with all the necessary Batteries and other appurtenances in a CONVENIENT and COMPACT form.

By means of a switch, which is now placed on each instrument, they can be worked as desired, either as the open or the ordinary continuous, or closed circuits.

It is intended especially for the use of

STUDENTS, AMATEURS, AND OPERATORS,

but will be found to be equally well adapted for use on

PRIVATE TELEGRAPH LINES,

or Short Lines of any description, which are not over three or four miles in length.

A NEW FORM OF BATTERY

is employed, which is compact, efficient, and economical, and especially adapted to the purpose for which it was designed. Each instrument will be accompanied by a

BATTERY, CHEMICALS, INSULATED WIRE

for connections, together with an

ILLUSTRATED BOOK OF INSTRUCTIONS,

which in itself forms a complete elementary treatise upon the ART OF TELEGRAPHY.

PRICES:

Single Instrument, complete, with Batteries, etc.....$8 00
Two Instruments, " " " " 15 00

Sent by Express on receipt of price.

Remittances may be made by Post Office Order, Registered Letter, or Draft payable to our order. Persons ordering Instruments will please write plainly, giving Post Office, County, and State, with instructions for shipment. Address,

F. L. POPE & CO.,
P. O. Box 6010. 80 Broadway, (Room 51,) New York.

THE NONPAREIL TELEGRAPH APPARATUS may be procured through the leading dealers in Telegraph Supplies throughout the country.

☞ SEND FOR A CIRCULAR. ☜

16,000 MILES

OF

"JOHNSON'S" WIRE

USED BY THE

TELEGRAPHS OF THE UNITED STATES

DURING THE YEAR 1871.

This is sufficient refutation of all the intimations thrown out by the Manufacturers and Importers of other Wires, reflecting upon the acknowledged superiority of the Wire manufactured by

Messrs. RICHARD JOHNSON & NEPHEW,

MANCHESTER, ENGLAND.

Their Works are the Largest in the World.

The great advantage which they possess over other manufacturers is their patent process of drawing Wire in great lengths (averaging 1,200 feet).

All Telegraphers know that, in nine cases out of ten, breaks in Wire occur at joints, hence the less joints the fewer breaks.

Messrs. RICHARD JOHNSON & NEPHEW furnish three-fourths of all the Telegraph Wire used by the

ENGLISH GOVERNMENT.

This Wire is necessarily subject to the tests, etc., imposed by the English Post-office Department.

A large stock always on hand and for sale at the lowest market prices—both free and in bond.

AMERICAN FIRE ALARM

AND

POLICE TELEGRAPH.

GAMEWELL & CO., PROPRIETORS,

NO. 104 CENTRE STREET, NEW YORK.

J. W. STOVER,
General Agent and Superintendent.

L. B. FIRMAN, Chicago, Ill.,
General Agent for the West and North West.

J. R. DOWELL, Richmond, Va.,
Special Agent for Virginia and North Carolina.

J. A. BRENNER, Augusta, Ga.,
Special Agent for Georgia and South Carolina.

L. M. MONROE, New Canaan, Conn.,
Special Agent for New England.

This system of Fire Alarm and Police Telegraph, with a Central office, or upon the

AUTOMATIC PLAN,

is now in operation in the following cities, to which reference is made for evidence of its great SUPERIORITY, VALUE and UNIFORM reliability:

Albany, .N Y.,	New Orleans, La.,
Alleghany, Pa.,	New Haven, Conn.,
Boston, Mass.,	Newark, N. J.,
Buffalo, N. Y.,	Omaha, Neb.,
Baltimore, Md.,	Philadelphia, Pa.,
Chicago, Ill.,	Pittsburg, Pa.,
Cincinnati, Ohio,	Portland, Me.,
Columbus, Ohio,	Peoria, Ill.,
Cambridge, Mass.,	Providence, R. I.,
Charlestown, Mass.,	Quebec, L. C.,
Covington, Ky.,	Rochester, N. Y.,
Detroit, Mich.,	Richmond, Va.,
Dayton, Ohio,	Indianapolis, Ind.,
Elizabeth, N. J.,	St. Louis, Mo.,
Fall River, Mass.,	St. John, N. B.,
Fitchburg, Mass.,	Springfield, Mass.,
Hartford, Conn.,	San Francisco, Cal.,
Jersey City, N. J.,	Savannah, Ga.,
Louisville, Ky.,	Syracuse, N. Y.,
Lawrence, Mass.,	Troy, N. Y.,
Mobile, Ala.,	Toledo, Ohio,
Montreal, Canada,	Toronto, Canada,
Milwaukee, Wis.,	Washington, D. C.,
New York City,	Worcester, Mass.,
Lynn, Mass.,	New Bedford, Mass.,
Lowell, Mass.,	Bridgeport, Conn.

The distinctive features of these systems of

FIRE ALARM AND POLICE TELEGRAPHS,

ARE,

First—The AUTOMATIC SIGNAL BOXES, the simple electro-mechanism of which enables any one—even a child—to give an *instantaneous, general,* and *definite* alarm of fire.

Second—The AUTOMATIC REPEATER, through which the apparatus may be distributed in a combination of circuits, and the entire system successfully worked without the constant personal attention of either operators or watchmen.

Third—The ELECTRO-MECHANICAL BELL STRIKERS, adapted to produce the full tone of the largest church or tower bells.

Fourth—The ELECTRO-MECHANICAL GONG STRIKER, for hose and engine houses, by means of which the location of the fire is instantaneously communicated to the members of each fire company.

These features combined form the

ONLY PERFECT, COMPLETE, AND RELIABLE SYSTEM

OF

FIRE ALARM TELEGRAPH IN THE WORLD.

Messrs. GAMEWELL & CO. are the owners of the original *FARMER AND CHANNING PATENTS*, one of the most important of which has just been extended for seven years. During the past seventeen years they have spared no expense or effort to secure improvements, and the systems are now covered by

MORE THAN TWENTY PATENTS.

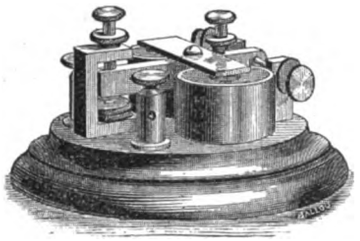
The introduction and operation of the

AUTOMATIC SYSTEM

involves so little expense, compared to the benefit which it confers, that even small communities can profitably adopt and maintain it.

The co-operation of TELEGRAPHERS in securing its introduction into their localities is cordially invited, and their efforts will be duly appreciated and compensated.

Any information desired in regard to the above system will be cheerfully and promptly furnished upon application at the office.



A pamphlet setting forth more fully its advantages and superiority, has been printed, and will be supplied to Municipal Authorities and others interested in Fire Alarm and Police Telegraphy upon application as above.

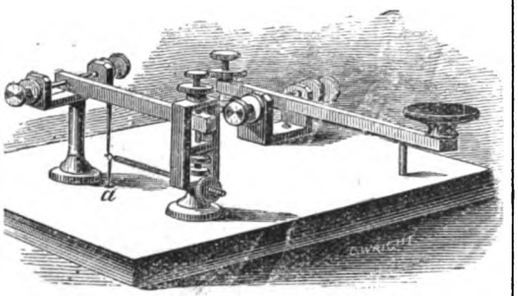
Materials for Private Telegraph Lines,



With instructions for putting up and operating.

M. A. BUELL,

26 Waring Block, Cleveland, Ohio.

MECHANICAL TELEGRAPH INSTRUMENT

PATENTED MAY 31st, 1870.

For Students, Colleges, &c. No battery required. An ordinary key and sounder is placed upon a proper base. The sounder is moved by a lever under the base, connected with the key, making a perfect instrument for those wishing to learn the Art of Telegraphy. An expert could not tell, without examining it, that the instrument was not worked by a battery.

It should be introduced into every school and family where there are those who wish to learn the Art.

Hundreds of persons throughout the country desire to become expert Telegraphists, and are constantly seeking permission to practice in the various telegraph offices.

This instrument is an outgrowth of this pressing demand. The Inventor is himself a practical operator, now in active service. Operators and others wishing to teach or learn the Art, will be delighted with this instrument.

It can be placed anywhere, as it does not occupy a space more than six inches square.

Its cost is but $7, and there is no expense whatever to keep it constantly in working order.

We will send a copy of SMITH'S MANUAL, free of charge, with each instrument, to individuals or clubs. The instructions in this Manual are particularly adapted to those who wish to learn by sound.

Special and liberal terms to manufacturers.

Remittances can be made by certified draft on New York, Cleveland, or Pittsburgh, money by express, charges paid, post office order, or registered letter at our risk.

Parties ordering instruments, from points except well-known cities, will please give the name of county and State.

Price, $7. Silver Plated, Extra Finish, $10.

Address, D. W. PUTT & CO., Wellsville, O.

D. W. PUTT,
P. BRUNER,
W. G. BROWNSON.

These instruments can also be procured at the same price from L. G. Tillotson & Co., New York; Bliss, Tillotson & Co., Chicago, Ill.; Chas. Williams, Jr., Boston, Mass.; M. A. Buell, Cleveland, O.

WIRE IN BOND.

For the accommodation of the

SOUTH AMERICAN, CUBAN and MEXICAN TRADE,

we shall hereafter keep a stock of the Celebrated

"JOHNSON" WIRE,

both plain and Galvanized, in Bond, ready for shipment from New York.

PRICES AS FOLLOWS:

No. 9, Plain Annealed	4½ cts. Gold.
No. 9, Galvanized	5¼ "
No. 8, Plain Annealed	4¾ "
No. 8, Galvanized	5 "

This Brand of Wire is the best in the world, and has been adopted exclusively by the Western Union and many other Telegraph Companies.

We also continue to import this Wire for use in this country, notwithstanding the high rate of duty imposed by Congress in the interest of the monopolists. Any amount of it can be seen at our store at all times. The import duty on wire is now two cents per lb. gold, and 15 per cent. *ad valorem.*

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 9. NEW YORK, APRIL 1, 1872. WHOLE NO. 106.

PRIMEVAL PRESENTIMENTS OF THE ELECTRIC TELEGRAPH.

One of the most extraordinary facts in the whole history of the Sciences and Arts, is the strong presentiment which existed for a century or more at the revival of learning that magnetism would be used to convey intelligence without regard to time or space. Just as there is now a kind of presentiment that electricity will supersede steam, or just as it was long thought a philosopher's stone would one day be discovered to turn all things to gold, or an elixir of life to banish old age, so the magic girdle which connects land and land beneath the waves of the ocean was not unknown to the scientific dreamers of the Baconian age.

Fifty wild things, indeed, are anticipated for the one thing which turns out true. The squaring of the circle, the *perpetuum mobile*, sympathetic cures and the whole budget of paradoxes have agitated the brains and excited the hopes of unfortunate genius for centuries back, but now these things are acknowledged to be illusory and impossible. And yet that which might have seemed most illusory and impossible is an accomplished fact.

In his very interesting account of the gradual triumph of the electric telegraph, Mr. Dodd has referred to this strange presentiment, and has given a quotation of the passage in the Prolusiones, of Strada, published in 1617, which describes in the most exact manner the working of the telegraph in 1867. Let a person who has used the latest form of Mr. Wheatstone's household letter telegraph try to describe the procedure, and we think he could not describe it better than in the following words:

"If you wish your distant friend, to whom no letter can come, to learn something, take a disk, or dial, and write round the edge of it the letters of the alphabet, in the order in which children learn them, and in the centre place horizontally a rod, which has touched a magnet, so that it may move and indicate whatever letter you wish."

A similar dial being in the posession of your friend.

"If you desire privately to speak to the friend whom some share of the earth holds far from you, lay your hand on the globe, and turn the moveable iron as you see disposed along the margin of all the letters which are required for the words. Hither and thither turn the style and touch the letters, now this one, and now that. * * * Wonderful to relate, the far distant friend sees the voluble iron tremble without the touch of any person, and run now hither, now thither; conscious, he bends over it, and marks the teaching of the rod. When he sees the rod stand still, he, in his turn, if he thinks there is anything to be answered, in like manner, by touching the various letters, writes it back to his friend."

No wonder that Strada, as he finishes this description, should break forth into prayer:

> "O utinam hæc ratio scribendi prodeat usu!
> Cautior et citior properaret epistola, nullas
> Latronum verita insidias, fluviosque morantes."

"O would that this method of writing might be brought into use! More safely and swiftly would the letter be speeded, fearing neither the snares of robbers, nor the delaying rivers."

Mr. Dodd suggests that in this wonderful description Strada was merely giving play to his imagination. In the midst of Strada's classical trifles, it was doubtless a mere play of the imagination. When Addison, in the *Spectator* (No. 241), alludes to Strada's description, he speaks of it as "an account of a chimerical correspondence between two friends by the help of a certain loadstone:"

"If Monsieur Scudery," he continues, "or any other writer of romance, had introduced a necromancer, who is generally in the train of a knighterrant, make a present to two lovers of a couple of these above-mentioned needles, the reader would not have been a little pleased to have seen them corresponding with one another when they were guarded by spies and watches, or separated by castles and adventures. In the meanwhile, if ever this invention should be revived or put in practice, I would propose that upon the lovers' dial plate there should be written not only the four-and-twenty letters, but several entire words, which have always a place in passionate epistles."

But though in the hands of poets and literary men this notion of a space-destroying telegraph was a fanciful chimera, among the scientific men of the day it was gravely discussed or mysteriously hinted at. From about the middle of the sixteenth to the end of the seventeenth century it is alluded to in most works on magnetism, and many other books of science. The Marquis of Worcester was a diligent collector of all the ingenious notions of his age, and he probably alludes to magnetism when he speaks of "intelligence at a distance communicative, and not limited to distance, nor by it the time prolonged" (Drich's "Life of Worcester," p. 357).

Sir Thomas Browne, in his "Pseudodoxia Epidemica," says of a supposed magnetic telegraph that "the conceit is excellent, and if the effect would follow, somewhat divine." He speaks of it as a conceit "whispered through the world with some attention, credulous and vulgar auditors readily believing it, and more judicious and distinctive heads not altogether rejecting it." But it would appear that, like a true-fellow-countryman of Bacon, old Sir Thomas submitted the thing to the test of experiment, and though the needles were at the distance of but half a span, when one was moved "the other would stand like Hercules's pillars." He also raises several objections to this supposed telegraph, such as that the needles would move contrary ways, and the difference of longitude would prevent two persons from watching their telegraph needles exactly at the same moment.

Joseph Glanvill, in his "Scepsis Scientifica" (1665). devotes a chapter to considering three instances of reputed impossibilities. One of these is the magnetic telegraph, which he describes as composed of sympathetic needles and an abecedarian circle. He mentions and controverts the objections of Sir Thomas Browne, suggesting that "there are some hints in natural operations that give us probability that it is feasible." And it is with a strange feeling of wonder that we find a writer two hundred years ago concluding in these words: "Though this pretty contrivance possibly may not yet answer the expectation of inquisitive experiment, yet it is no despicable item, that by some other such way of magnetic efficiency, it may hereafter with success be attempted, when magical history shall be enlarged by riper inspections; and 'tis not unlikely but that present discoveries might be improved to the performance." The predictions of men are not often so cautiously stated or so completely fulfilled, that we can afford to overlook a sentence such as the above.

Gilbert, the cotemporary of Bacon, and the founder of the science of magnetism, does not allude to this imaginary telegraph, so far as we can find, or if he does, he dismisses it, among other fancies, as unworthy of his great treatise, "De Magnette." Much about the same time (1629) Nicholas Cabeus, the Jesuite of Farrara, wrote his "Philosophica Magnetica." "It is a fable," he says, "that two men can converse with each other between the most remote and separate places, by the aid of two revolving needles," and he considers that those ought to be severely castigated who, with such portentious fables, deter men from the study of true causes. Such an effect, he says, cannot be produced by magnets, and he proves the fancy to be an error, "lest any one should be deluded by a vain hope." Vague and erroneous though the notions of a telegraph then were, they were truer then the refutation of Cabeus, grounded on the false principle that "every physical agent determines for itself a certain sphere of activity, beyond which it cannot have any influence."

But the interesting question remains, to whom is due the first suggestion that intelligence may be conveyed by magnetism or electricity? Strada attributed it to the celebrated Cardinal Bembo, the Secretary of Leo X. But Bembo, who died in 1547, was a historian and literary characrer, and would hardly be likely to form so new a conception, of a purely scientific kind.

The earliest work in which we have been able to trace the discription of the supposed telegraph is the celebrated "Natural Magic," of the Neapolitan Paptista Porta, published in the year 1589. This work is a collection of all that was most wonderful in the sciences, then aroused from a long sleep in Italy. His seventh book is on the "Wonders of the Magnet." In the preface he enumerates these wonders, such as the mariner's compass, the perpetual motion and the sympathetic needles. "I do not fear," he says, "that with a long absent friend, even though he be confined by prison walls, we can communicate what we wish by means of two compass needles circumscribed by the alphabet." A few lines before, we find him mentioning, with great respect, Marco Polo, the source of some of his information. But in het eighteenth chapter of the same book we get more, probably, to the origin of the notions in question. The fact that if a magnet be placed beneath a table, it will affect a magnetic needle above the table, in spite of the intervening matter, is mentioned by

Digitized by Google

Porta with much wonder. This is the experiment which seems to have suggested the power of two magnetic needles to act upon each other at a distance, even though prison walls intervened. And strange to say, this experiment may be traced back to the great St. Augustine. "Novit hoc experimentum Divus Augustinus," says Porta, and an exact description will accordingly be found in Augustine's treatise "De Civitate Dei," a work believed to have been begun A. D. 413.

It is the fashion in these days to fall into raptures of wonder and exultation over the magnetic telegraph, but it is not we who have first wondered. Pliny counted the loadstone as the most wonderful thing in nature. "*Quid enim mirabilius?*" he asks. "Iron is the strongest thing in nature, and yet before the magnet it becomes docile," he reflects, "*cedit et patitur mores.*" All ages, then, have shared in the intelligent wonder excited by the powers of magnetism. It is only the riper inspections of this age that have carried out to the letter the anticipations of former ages. The telegraph of the present time tends to assume exclusively the form most nearly analagous to the conceptions of Porta. The earliest attempts at electric telegraph, as Mr. Dodd well relates, were made with frictional electricity, which is not applicable to the purpose. Then galvanism was studied, and the conducting powers of metalic wires became understood. Now, the most improved telegraphs consist essentially of a magnet moved in front of one end of a wire, and a magnetic needle which is thereby made to move in front of the other end of the wire. And though a wire is quite indispensable to conduct magnetic influence in one direction, it is a fact that the return current passes back without a wire, through land and sea, stayed neither by wall or mountain, as Porta imagined to himself.

The time is rapidly approaching when Ariel's girdle will be completed, and signals be transmitted round the world in a moment. It is idle, perhaps, to suggest that Shakespeare may have had some thought of magnetic communication when he conceived that fantastical idea. Certain it is, however, that the conceit of a space-destroying telegraph was "whispered through the world with some attention" in his age, and we have thought this to be a fact worthy of being a little better known.—*London Spectator.*

CONTENTS OF DISPATCHES—GIVING TESTIMONY.

Giving testimony in court as to the contents of dispatches has always been a delicate matter, and one respecting which too much care cannot be taken. An operator can never know the full scope of the meaning of a message. It was never designed he should know. The telegraph company, president, operator, messenger, and all, are so much machinery put in motion to do a certain thing, in which they have only the duty of the engine on a steamboat, or the locomotive on a train, or the engineers of either. No officer of a telegraph company has a right to refuse a properly-written dispatch, when the tariff is offered for sending it, and when sent, he has no right to show it to any one, to speak of it to any one, or in any way make use of it, except to preserve it safe from every eye, and to resist any change in its possession. So far, an operator's duty is presumed to be generally understood, although it will do no harm to reiterate the nature of that duty, as we now do. There are some operators so garrulous, so full of the importance of an acquired secret, that they seem incapable of retaining it, and by all the well-known useless cautions of secret-tellers, let it out to favorite ears, as strictly confidential, and soon make it as common as the town clock or an alarm of fire. To such it will be no harm to say what we have said as to the absolute inviolability of dispatches. On this head, the Legislature has made a most emphatic movement, and an operator, or any one else, divulging or obtaining improperly the contents of a dispatch is made liable to a fine of $500 to $1,000.

The object of this article is to relate the case of an examination in the Superior Court, New York city.

The Telegraph Company was subpœned to produce a dispatch written some five years before, and its agent accordingly presented himself, was sworn, and requested, after some preliminary questioning, to read the message.

Witness refused.

Counsel then asked witness to give him the dispatch to read.

Witness refused.

No appeal meanwhile had been made to the judge, to whom, however, after refusal to deliver to the counsel, witness was willing to give the dispatch on his demanding it, stating that the judge's authority was the only one he could recognize. On appeal by both the counsel in the case, the Judge remarked as follows:

"This case is new, and I am not aware of any decision having been made under such circumstances. I am compelled, however, to hold a telegraph dispatch as inviolable, unless its contents become essentially necessary to the ends of public justice. The telegraph company cannot divulge, except on compulsion, any message in its possession without crime. It occupies a most sacred position as the depositary of innumerable secrets, which it can no more divulge than a man can be compelled to divulge his most confidential family affairs, or than a priest can be required to divulge the secrets of his communicants. I therefore approve of the refusal to read or allow to be read the dispatch which witness appears to have in his possession, unless it finally appears that justice is in danger without it. I shall, however, direct the clerk to take a copy of this dispatch, to be held by him as the property of the court only, and subject alone to its call and inspection, and to none other without its authority."

The dispatch was thereupon copied, the original handed to witness, and he was released.

OCEAN TELEGRAPHY.

[From the London Standard.]

The following letter is being circulated among the shareholders of the Anglo-American and French cable companies:—

GENTLEMEN—I submit, on behalf of myself and some of the largest shareholders in both companies, the accompanying scheme for complete amalgamation (the result of many months' careful consideration), and I recommend it to your earnest and immediate attention, on the following grounds:—1. Complete unity of interest and action in all matters. 2. Large saving in working expenses. 3. Considerable profit on the lease of the Newfoundland lines at seven per cent. in lieu of the present arrangement. It has been ascertained that the Newfoundland Company will accept these terms. 4. Greatly increased confidence of investors from having four cables in one interest. 5. The certainty of uninterrupted communication—a matter equally important to the shareholders and the public. 6. The application of our reserve fund to the redemption of our seven per cent. debentures, instead of lending money on other securities, and the giving us all the benefit of a fourth cable at once in anticipation of future reserve. 7. The exclusion of new competitive schemes. 8. The gradual reduction of rates for messages, which our increased carrying power would enable us to concede to the public. Thus in every way the proposed amalgamation is of the greatest advantage to us as shareholders, as well as to the public; and, on the other hand, in no conceivable way can it be of any disadvantage. I enclose a form of assent to the proposed scheme, and shall feel obliged by your forwarding it to me, filled up, without delay. It is not a form of proxy, and does not prevent you from giving your assent to any modified scheme. It merely asserts the general principle that we ought to obtain all the benefits to be derived from amalgamation. I am, sir, yours, obediently.

January 11. WILLIAM FORD,

ATLANTIC CABLES COMPANY (LIMITED).

Capital, £5,550,000, consisting of £2,775,000 seven per cent. preferred stock, and £2,775,000 deferred stock. Debenture capital, £1,000,000, with power to increase on additional cables being laid. The Anglo-American shareholders to receive for each £100 of Anglo-American stock £100 seven per cent. preferred and £100 deferred stock. The French cable shareholders to receive £100 of preferred and £100 deferred stock for every five shares in their company. The Newfoundland company to be leased at seven per cent. guaranteed dividend. A fourth cable to be laid to Halifax or such suitable point as may be agreed upon at a cost of £1,000,000. This amount is to be raised in seven per cent. debenture stock, redeemable at £110 by an accumulative sinking fund of three per cent. The results to the shareholders are estimated thus:—The traffic has now fairly reached £2,000 per day, and certainly will not be less than this in 1872, probably much more. This gives a gross traffic of per annum, £730,000. The working expenses of the three companies will not exceed and may be reduced below £100,000, leaving net £630,000. The rental of the Newfoundland lines, £56,000—£574,000. The debentures and redemption for the fourth cable will not come in until 1873; but assuming this as a charge in 1872, £100,000; surplus for dividends, £474,000. Seven per cent. preferred dividend, £194,000, leaving for the deferred stock, £280,000—£474,000, or fully twenty per cent. dividend. It is proposed that the fourth cable shall be connected directly with Liverpool, Manchester, and the manufacturing districts, so as to remove an existing grievance.

MESSRS. HURD & HOUGHTON, of New York, representing the Riverside Press, Cambridge, have in press a reprint of all the cases relating to the liability of Telegraph Companies, chronologically arranged from the English, Irish, and American Reports, with notes and references.

COVERING WIRE WITH RUBBER, ETC.

A foreign exchange describes as follows: a new invention for covering wire with India-rubber, and similar substances, and for making tubing of the same:—"The machine, more particularly designed for covering telegraph wire with insulating material, comprises a cylinder for holding the India-rubber or other gummy substance, and in this cylinder a screw of the same or nearly the same diameter extends through one end, and is supported in bearings and rotated by gearing applied outside the cylinder. At one end of the cylinder is placed the die through which the substance or compound is forced, to form the covering or tube, and through which the wire and the substance pass together. The die is arranged at a right angle to the axis of the cylinder, so that the wire passes transversely across the end of the screw, or at a right angle to its axis. In a line with the die and inserted through the opposite side of the extension piece, is a tubular guide, through which the wire to be covered is admitted and passed to the die. At the rear end of the machine is placed a thrust-pin to receive and sustain the end of the screw against the back pressure. The thrust-pin is formed with a screw-thread, and is thereby adjustable in a socket fixed on the machine."

PHOSPHORESCENCE PRODUCED BY FRICTIONAL ELECTRICITY—M. Alvergniat states that if a little bromide or chlorid of silicium is introduced into a glass tube, and the tube is then exhausted and sealed, friction with a piece of silk, or even with the fingers, produces a beautiful phosphorescence, which is rose colored if the chloride is contained in the tube, and a yellowish green with the bromide. The induction spark produces no light within these tubes unless the vacuum is very perfect, but in that case the phosphorescence disappears.

RAILROAD TRAIN ORDERS.

AURORA STATION, February 23, 1872.

To the Editor of the Journal of the Telegraph:

SIR: In your issue of February 1st, No. 5, I read with interest three articles in regard to the use and abuse of railroad wires. I am, like T. D., open to conviction. Like him, I can see no safe remedy in Observer's plan; on the contrary, more risk to the railroad company, more danger to human life and to property, where the orders are not repeated. When an order is presented to the conductor and engineer of a train, and their understanding of it repeated back to the dispatcher in charge, and his O.K. received, there is no possibility of any misunderstanding or any mistake, and nothing but the negligent violation of a plain order can in any way cause an accident, excepting, of course, the usual breakage of rails or running gear—things which are unavoidable.

When not repeated back, this security is gone; for, as T. D. says, one operator might give it O.K. and the other one not. I have known instances where two copies of the same order were made by the same operator, and the one given to engineer different from the one given conductor on a repeated order, where the train did not stop and the orders handed to both as they passed, so as to save the conductor a walk over his train to know what his orders were. So, to me there seems more danger where two operators are concerned than where only one is concerned. I may be wrong, and would like to be enlightened if I am. Certainly it would be an advantage to the profession, for better operators would have to be employed and better wages paid. Another Observer says there are cases where one sending would do for both trains. Yes; but for safety have both repeated back. That would save the dispatcher one sending and make it sure, as he could correct any mistake or misunderstanding that might occur in either.

This would remove the responsibility from both the dispatcher and operator. I, for one, want no responsibility of an unrepeated order on my shoulders, and, I think, no other operator does. Possibly Observer does though. Then there is usually more to go in one order than in another; so that there has got to be two sent, or one will contain more than is needed.

For the information of Green Flag, I would say his two orders could be done away with and one made to answer, by having operator copy the order to C. and E. No. 2 at B, which would inform him that No. 2 had right of track over No. 1 to A, upon receipt of which he would put out his green flag, and, upon the arrival of No. 1, show the C. and E. the order, who would then understand that they could proceed no farther until the arrival of No. 2.

Yours, truly, OPERATOR.

THAT'S WHAT'S THE MATTER.

To the Editor of the Journal of the Telegraph:

I have noticed the controversy in the last two or three numbers of the JOURNAL, and have been waiting—very anxiously—to see some one write upon a subject which is of far greater importance than any yet named, viz.: the necessity of operators being secured who are in every way competent. There cannot be too much care or precaution used in the Despatcher's department, in running trains by telegraph. I have had fifteen years' experience in railroading and telegraphing, and this experience tells me that the safest way is the best. My plan would be this:

The Despatcher's first duty should be to secure for his operators men who are *competent*, and who can be depended upon. Men who, when they receive an order, *know* exactly what it requires and what they are to do with it. This can easily be accomplished by paying salaries worthy of such talent. No first-class man is going to serve a corporation that does not compensate his services to their full value. There are plenty of good men who can be found, but they will not work at *starvation* prices. Railroads should think for a moment what they require, and then look at the salaries they pay. After a Despatcher has secured such men his work is easy, and the length of time consumed in giving orders is reduced very materially. In regard to the manner of despatching trains, my view is to first be sure you have the train under your control which *has the right of road*. This can be done by sending the order to the conductor and engineer of said train, giving them a positive order "not to pass a certain point, &c;" or, what would be better where the Despatcher has the right kind of men, giving the order direct to operator, and get his "13," and then order the other train to proceed. This view may look as though it took a great deal of time, but such is not the case. Where the operators are proficient—*as they should be*—two or three minutes is full time to give these orders.

I notice some of your correspondents dictate orders in this wise: "To conductors and engineers Nos. 1 and 2: trains Nos. 1 and 2 will meet at A." He goes on to say, "This would hold No. 1 at 'A' until No. 2 arrived, and give No. 2 the right to run to 'A' regardless of No. 1." I beg leave to differ with him there. No. 1 being the train which has right of road No. 2 has lost her rights and hence *cannot* proceed on this order, and only can run against No. 1 on a *positive* order in so many words giving her the right to run against the train which is on its rights. Where does No. 2 get these rights per his order? Her schedule rules give her a certain number of minutes as her limits, and after she loses this limit, she has no right to proceed against said train until she waits the prescribed limits of the other train, and then, if it has not arrived, she can proceed with caution, flagging all curves and running slowly, until other train is met, which, per its schedule rules, is doing in like manner. This is the way we railroaded before the telegraph was brought into requisition, and what was the telegraph brought into use for, if not to obviate this delay of waiting and trouble of flagging? And how does it give the train the right to run which has no schedule rights to run on, unless it gives a positive order to run? I think there are *many* Despatchers who will bear me out in my view of the case. Another thing Train Despatchers should have the exclusive use of the wire on which they run trains. As there are times when but few orders are necessary, trains being "on time," so there are times when a great many are necessary, and, as in train orders, haste and despatch are required, or else the orders do not assist trains over the road.

I agree with one of your correspondents in regard to the Despatcher knowing the road. He should not only know the road, but he should know where every heavy grade and bad portion is, and the length of every siding, and the capacity of every engine for pulling trains and making time. I would not undertake to "run trains" on any road that I was not acquainted with the above facts, and some others of minor importance. In regard to commercial business being delayed, I think that anyone who will consider all the points will find it the best plan to have a separate wire for this business, especially on a railroad that has a number of trains and does a heavy business. Still, if competent men are employed, there will be found many intervals where commercial business can be got off. Speaking of competent men reminds me of an incident which came under my observation four or five years ago. A road on which I was then employed, at one of its general offices, contracted the habit of "cutting down salaries" at its way stations, and "Jewing" operators, until finally those along its line, at way points, were not even respectable "plugs." The result was that in one week there were *five engines and a number of cars smashed up, two* of the *engines* being on their *first trip* over the road. At the time of the last collision the Superintendent of the road was in my office, and when I told him of it his reply was, "D——n them thirty-five-dollar operators." He thought it, too, for investigation showed that correct orders had been given, and in some of the cases had been neglected as to delivery, and in others had been repeated correctly, and "O K" given, and then operator made *mistake in "copying."* But what more could be expected of men who could not make the alphabet *correctly*. Let roads and corporations pay men who are competent, wages they deserve, and there will be more safety and less grumbling.

Yours, "OLD MAN."

OUR old friend Charles W. Temple, Telegraph Superintendent, Vincennes, Ind., has been promoted to be assistant Superintendent of the Eastern Division of the Ohio and Mississippi R. R. Mr. Albert Hayward succeeds Mr. Temple in the care of the Telegraph, and for which he is fully competent.

TARIFF BOOKS.

INDIANA, February 28, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—I see that some one has brought up the subject in regard to copying tariffs. Now wouldn't it be better to have blank leaves furnished to each office, instead of having new books issued. I don't think it would hurt any of our feelings if it should be done; besides, it would not cost so much as it would to have new books issued every month or two, and would do away with needless blotting and scratching out. Hoping this will have your attention.

I remain, as ever, your friend, J. B.

RUNNING NOTES BY A MANAGER.

While on a recent visit to some friends in Poughkeepsie, up the Hudson, curiosity led me to visit the summer residence of Prof. Morse. It is a little more than two miles out from the town, in a northerly direction, on South avenue. The House, a large gothic wooden frame building, standing away back from the street, some two hundred and fifty or three hundred yards, is hardly to be seen, surrounded as it is with large locust trees. The place is very appropriately called "*Locust Grove.*" A fine view of the surrounding country is to be had from the rear of the house, which overlooks a deep valley and fine scenery.

The hot houses were a treat to go through, with fragrant flowers in full bloom. The place is in charge of Tom Devoy, an excellent gardener, who on several occasions has carried off first prize for the cultivation of grapes. He has been sixteen years with the professor, and during all this time, Tom has never heard a cross word from him. No more faithful or worthy man could be found.

The grounds cover some seventy-five acres, are in excellent order, under good cultivation, with five outhouses, such as ice house, stables, sheds, carriage houses and barn, and all probably worth $90,000.

It is possible Mr. Morse and family may spend this summer at some watering place and not at "Locust Grove."

Mr. Morse's city residence, is No. 5 West 22d street, New York, where he spends the winter. H.

SOCIETY OF TELEGRAPH ENGINEERS.

This young, but welcome and necessary addition to the list of scientific, learned and technical societies, held its opening meeting on Wednesday evening at half-past seven. By favor of the Institute of Civil Engineers, the use of their noble hall was granted for the occasion, and a numerous attendance evidenced the interest taken in this practical inauguration of what will, we doubt not, prove to be a most valuable society. We noticed, some four or five months since, the establishment of the society, and the formation of a council, code of rules, &c. Mr. C. W. Siemens, D.C.L., F.R.S., the president, took the chair on Wednesday, and delivered his inaugural address, which we shall notice at length next week. He adverted to the delay that had taken place in convening the opening meeting, which he explained was in the permanent interests of the society, and further pleaded for an act of indemnity from the general body of the members, in condonation, *ex post facto*, of certain transactions of the council, diverging somewhat from the course prescribed at the outset, especially in relation to the class of foreign members, who are to have all the privileges of affiliation on payment of an annual subscription of £1 sterling. The cordial and unanimous response granted by the assembly, as also in the matter of election of new members by show of hands in lieu of by ballot—somewhat informal—supplied a gratifying endorsement of the action of the representative body. The rules drawn up by the council were accepted as the statutes of the society, twenty-three new members were elected, and the announcement was made of the accession, as foreign members, of all, or nearly all, the delegates at the recent Telegraphic Congress at Rome. The subject of the first paper will be "On Automatic Instrumentation," by Mr. Culley.

FAMILIAR TELEGRAPH TALKS.

As we have been talking somewhat freely about magnets and their care, let us say something more on the general subject. Magnetism is to form the basis of great developments some day, just as now it is one of the grand powers of the universe. How grand, for example, is the thought that yon quiet sun, ninety-five millions of miles away, holds this great earth within firm hold of its magnetic grasp, and that the quiet moon, 294,000 miles away, ridges up our oceans, and dashes the mighty waters up and down the fretted shores with their everlasting tides!

1. Pieces of iron or steel, which have long remained in a north and south position, become magnets, having acquired the power of attraction and repulsion. As this is so, and as it is also true that a magnetic needle always points north and south, when left free, it shows that the earth's electric currents go east and west, the magnetic needle always taking the direction opposite to the direction of the current. Thus, the magnetic power is in the opposite line of direction to the line of the wire. This has led to the idea, that lines of telegraph running east and west, work better than those running north and south.

2. The turning of a freely poised magnetic needle north and south, is called placing itself in the *magnetic meridian*. This means simply, that it points north and south. The point toward the north is the *North Pole*, so called; the other, pointing south, the *South Pole*. In France, this statement is reversed, the point toward the north being called, and which it really is, the south pole. In magnetic needles, the north pole is usually distinguished by a file cut across near the point. It is the negative pole, and is marked when illustrated, as N; and in electric works, is designated by the sign — in distinction from the south or positive pole +. It is important to remember these signs, as they are frequently employed by electricians.

3. If a magnet be brought near another magnet, and the north pole be presented to the north pole of the other, they will repel each other. The north and south poles attract each other. When soft iron is used, it is attracted equally by either pole, hence the value of always keeping the magnet core as soft as possible; and this is equally true of the armature.

4. What is called the *magnetic field*, is the space in the neighborhood of a magnet, within which it exerts a power on other objects.

5. It is curious, that in magnetism, as in human nature, the poles which attract are much stronger than those which repel, that is to say, when kept in that relation to each other. The magnetic faces tend to strengthen each other, just as friendship intensifies itself in two human hearts. The repellant poles have a different tendency. They say also that the marriages of persons of different natures are the most productive of happiness.

6. Iron receives magnetism quickly, but cannot retain it when soft and pure. This is what makes it so valuable in electro magnets, whose value consists in the ease with which they are magnetized and demagnetized. The latter is the quicker property of the two. Steel is not attracted as forcibly as iron. That is the reason that a hard core is sure to make a weak magnet. Steel, however, holds magnetism more or less permanently, which is a property not wanted in a relay. The strength of a permanent magnet depends on the hardness of the steel and the length of the bar. Iron, when impure or hard, retains what is called by electricians *residual magnetism*. It is well that these terms be made familiar.

7. If a steel bar, unmagnetized, is nicely balanced, and made to point east and west, it will remain level. Magnetize it, and the north end will dip or appear to become heavier. If placed east and west, no such change will appear.

8. The power of a magnet is at its maximum very near the ends or poles. There is no power at the middle. If a magnet is broken in two, each part becomes a complete magnet.

9. It is a curious thing that, in making what is called a *compound* magnet, *i. e.* a horse shoe permanent magnet, composed of several plates laid side by side, if one of the plates be weaker than its neighbor, it will not be strengthened by its strong companion, but weakened, and, indeed, have its character reversed! This puts us in mind of the Scripture saying, that "to him that has much shall be given, but to him that hath not, shall be taken away even that which he hath." So it happens that weak souls go under. A man has to carry himself stiffly these days or his back is broken.

10. The earth is an enormous magnet. It will demagnetize a magnetized bar which has been carelessly laid aside, without regard to its position in relation to the earth. This is the reason for the employment of what is known as a *keeper*, a piece of metal put across the faces of a magnet to preserve its power. These are also called *armatures*. The armatures become magnetized by induction, and, in their turn, induce magnetism in the bars. This mutual induction is more powerful than the inductive influence of the earth.

11. Magnetism acts through all substances not themselves capable of being magnetized. A compass in a brass or wooden box is as easily affected as if it were not so inclosed. In an iron box it would be a question of power, between the iron in the box and the magnet outside.

12. A wire through which a current is flowing possesses, for the time, properties similar in some respects to those of a magnet. It attracts iron filings, attracts or repels the magnet, and even acts upon other wires through which currents are flowing. This peculiar property last named, it will be seen in the first article in the JOURNAL, early gave the idea of telegraphic transmission.

13. Two parallel conducting wires will attract each other if the currents flow in the same direction in both, and repel if they flow in opposite directions. This would seem to point to the advantage of having two wires upon the same arms, worked by separate and opposite polarity, to prevent this natural sympathy of two loving hearts thus "flowing into one," and yet that would be the surest mode of causing the currents to mix.

14. Suppose one's feet to be connected to the copper, and one's head to the zinc pole of a battery, the current would flow upwards through the body. This shows the direction of the currents. If a magnetic needle be then placed before the breast, the north pole will move to the left hand at right angles to the body.

WONDERS OF ELECTRICITY.—The next volume of the richly-bound second series of the Scribners' popular Library of Wonders will be the "Wonders of Electricity," to be ready about the 20th. It is from the French of J. Baile, edited by Pres. John A. Armstrong, of the New York State Normal School, who has made numerous additions of great interest and importance. The book is, like the others of the series, exceedingly entertaining, while it gives full and accurate information as to telegraphing, the electric light, electro-plating, electric motive powers, and other applications of induction machines. Among the most interesting of its pages are those which describe the scenic effects produced by electricity at the Grand Opera, Paris. In the opera of "Moses in Egypt" these were very brilliant and ingenious, the prophet Moses being always surrounded with a radiant light, which seemed to come from his person, though really from an electric lamp at the wings. The difficulties in the practical use of electric engines are clearly explained, and indeed the volume is full of matter of both popular and scientific interest. There are sixty-five illustrations, many of them full-page and very fine.

COUNTING NAMES OF PLACES.

OFFICAL DECISION.

After answering the enquiry of Holley Springs in our last, which we did upon what we regarded as established usage, and also from what we knew of the original design of the rule, which we framed and reported at the convention of 1858, other enquiries came which we deemed it proper to submit to the Company's Electrician, who is charged with the duty of the interpretation of the rules, and from whom we asked an official decision. The following is Mr. Prescott's reply, which shows that we were in error:

ELECTRICIAN'S Office,
Western Union Telegraph Company.
NEW YORK March 21, 1872.

J. D. REID, *Esq.*:

DEAR SIR—In answer to your favor of the 19th, I would say, that I think you misconstrued the rule in your reply to Holley Springs' inquiry, published in the last number of the JOURNAL. According to rule nine, names of places are only to be counted as one word when used to designate places, that is, villages, towns, countries, &c. Of course the words United States, when prefixed to the word attorney, or marshall, are not used to designate a place in the sense of the rule, any more than when prefixed to hotel or Telegraph company, but are simply employed to assist in designating the office held by the persons employed to perform certain functions, and would be counted in the same way as Spuyten Duyvil Station Agent, or Postmaster at Peekskill on the Hudson. The only right the words United States have to be counted as one, is by virtue of their use in designating a place or country. When they are used to signify the nation, that is to say, the people of this country, they must, under the rule be counted as two words, and therefore when used in connection with any officer of the Government as United States Attorney, United States Marshal, or President of the United States, they should be counted as two words, because these functionaries are not officers of the country, the land or place known as the United States, but of the people, as for example, Louis Phillippe was never King of France, that is of the country or place, but King of the French, that is to say, of the nation.

Yours respectfully,
GEORGE B. PRESCOTT.

COUNTING DUPLICATE FIGURES.

CHICAGO, March 15th, 1872.

To the Editor of the Journal of the Telegraph:

In JOURNAL, some months prior to our big fire, you answered inquiry "how figures after words" should be counted; our files of JOURNAL OF THE TELEGRAPH previous to October 8 were destroyed by fire. A dispute has arisen here as to how to count: "Buy five hundred and eighty-five (585) shares." Will you please duplicate your answer of some months ago as our authority in the matter. Yours, &c., G. W. FELTON,
Operator.

Answer.—The rule is that, having counted the number of words used in stating a sum, as for example, the sum given in the inquiry of our correspondent, "five hundred and eighty-five," which is composed of five words, the figures used as an additional expression of the same sum shall be counted the same as the sum expressed in words, viz.: five words. The message quoted, therefore, has twelve words, i. e. ten words for the duplicated sum and two for the words "buy" and "shares." It will be seen, therefore, that the fact that the sum in figures requires only three characters to represent it does not decide the charge therefor, but is fixed by the number of words, as in the example given.

The reason for this rule is to discourage the use of figures in the body of messages.

TELEGRAPH WIRE TARIFF.

Before the Schenck Tariff act telegraph wire paid thirty-five per cent. duty. The firm of Washburn & Moens, in New York, conceived the laudable design of protecting the American telegraph wire-drawer against the pauper wire-drawer of Europe. Mr. Moens came to Washington early in 1870, and although he ostensibly lived at the Arlington, he nevertheless pitched his tent in the lobby of Congress. He besieged Congress much closer than the Prussians did Paris. After he had sat down before the committee rooms from January to June he carried the position, not by storm, but by strategy. It would never have done for him to put in even that outrageous Schenck Tariff bill that a duty of sixty-two and seven-eighths per cent. should be levied on telegraph wire when the duty then existing was only thirty-five per cent. He had, therefore, resource to a pleasing expedient. The duty on iron wire three-sixteenths of an inch in diameter, whether coated with metal or not, was already two cents per pound and fifteen per cent. ad valorem. He inserted in the infamous steel-rail section of the bill the following proviso:

Provided, That round iron in coils three-sixteenths of an inch or less in diameter, whether coated with metal or not so coated, and all description of iron wire and wire of which iron is a component part, not otherwise specially provided for, shall pay the same duty as iron wire, bright, coppered, or tinned.

Now, inasmuch as telegraph wire was never provided for in any tariff, and came in under the head of unprovided-for articles, paying thirty-five per cent., this ingenious clause of Mr. Moens did the business. Telegraph wire, instead of paying thirty-five per cent. duty as before, has now to pay two cents per pound and fifteen per cent. ad valorem, or together about sixty-three per cent. Such is the history of Mr. Moens' siege and victory. It is rather remarkable that soon after the passage of this act the workmen in telegraph wire demanded either an increase of pay or a reduction of the working hours; but they were less fortunate than their famous strategetical chief—they got neither. The only thing they did get was a strike, and to be starved into submission. And thus does a good Congress protect American industry. Equally remarkable and creditable is the fact that the Western Union Telegraph Company has to send to Manchester, in England, for its wire, not because they would not buy American wire, but simply because the protected American industry is unable to supply their full wants. The net result of our thus raising the duty on this indispensable material is that "American industry" thus protected in the person of the laborer does not make a cent by its Protection; and American industry after Protection is unable to supply the American market; and the only party which makes anything is the rich manufacturer like Mr. Moens. It would be hard to find a more typical example of what a swindle a protective tariff is.—*N. Y. World.*

ELECTRICITY *versus* THIEVES.—A novel, and, as it seems to us, very serviceable, door-fastening has been recently contrived in Berlin. It consists of electro-magnetic machinery for bolting the office doors from the manager's or cashier's desk, a knob being fastened to the desk or counter, by pressure on which the electric current is made to push a heavy bolt across the doors. The effect is instantaneous. The short period employed by a thief or forger in gaining the door, in some cases, suffices for his detection, and, in that event, his escape might be effectually cut off. The machinery has been constructed to the order of a large banking firm in Berlin, in whose office it is now in use, though there has been no occasion as yet to test its powers otherwise than experimentally; but, when so tried, it has invariably given entire satisfaction.—*Handicraft.*

FROM ONE OF THE VETERANS.

DENVER, COL., Jan. 17, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR: One of the pleasant reminiscences of my telegraphic life is having been sent by you to take the place of "Uncle" John Horner as Receiver of the New York office in 1850, on account of a reduction in his salary, owing to the office not paying expenses. Experience proves that he did well to "stick." I sometimes think it would be very pleasant and profitable to have an organization of *Telegraphic Pioneers.*

Perhaps I would hardly be admitted, but I think I would come pretty near it. Such an organization might gather and preserve a great many interesting incidents and matters of historical interest—although I presume you could furnish a "History of the Telegraph in the United States" that would embrace almost everything of interest, including personal anecdotes, &c., &c. With best wishes for the new year, and hoping that many more may be added thereunto in your career, I am, very respectfully, Yours, B. F. WOODWARD.

We cannot believe we were ever guilty of trying to supersede our life-long friend and pitcher, and everybody's friend and pitcher, John Horner. We remember that times were very dry and salaries small. Just think of New York not paying expennses! And yet we had a wire direct to Cincinnati which was the wonder of the hour. John Horner! we ask your pardon. It must have been the result of the delicacy of "reducing" so good a man. It seems very ridiculous now. J. D. R.

BATTERIES IN FRUIT JARS.

We have succeeded in making a quite powerful series of half a dozen elements by using old fruit jars holding about a quart. The copper pole was formed, in the first place, of heavy tea-lead, which costs but little and is easily moulded to any form. As the power of the battery depends largely upon the extent of surface exposed by the copper, we folded the lead in ridges, thus obtaining a large extent of surface at the bottom of a comparatively small jar. We did not go to the cost of having zinc poles cast, but simply took a quantity of zinc fragments, coated them well with mercury, and piled them on a slice of wood, cut endwise off a block, and bored full of holes. The wood and its load were suspended by cords which were tied round the mouth of the jar. By using large jars it is possible to construct batteries of any power that may be required in the arts, and in this way odd scraps of amalgamated wire, that would otherwise be wasted, may be readily utilized. We may add that lead, thin sheet-brass, and even common tin-plate, may be employed for the copper pole of Daniell's battery, and will give quite as good results as pure copper—the fact being that in a very few minutes the entire surface of these metals becomes coated with a deposit of pure copper, and acts like copper.—*Handicraft.*

OWING to the scarcity of Operators at Alton, Ills, Mrs. B. of that place, is endeavoring to supply the want by instructing a young colored gentleman, "Kelly" by name, in the mysteries of the art.

HARRISBURG, Texas, March 15, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR: I notice in the columns of your inestimable paper considerable complaint about crowded tariff books. I think there is a remedy for this, and a simple one, and I would like to make a suggestion in that connection. When any part of the book now in use is filled, would it not be a good idea to rule a sheet of writing paper properly, to correspond with and paste between the leaves where required, and thereby provide space for all the new offices that would probably be opened in a year's time? It would certainly be an easy matter and but a few minutes' work; and, if neatly done, would not present such a bad appearance. I have adopted this plan, and find that it works like a charm; and, I believe, if brought into general use, would save much inconvenience to all and unnecessary expense to the company.

Respectfully, C.

RELAY JUSTIFIES HIMSELF.

CHARLOTTE, N. C., February 26, 1872.

To the Editor of the Journal of the Telegraph.

Please inform "One in Search of Right," (JOURNAL, February 15) whether or not Rule No. 20, authorizes or justifies Relay offices in "patching up" messages, by counting legitimate compound words as two words, and making a compound word out of two separate and distinct words, in order to make the number of words in message correspond with check.

Would you not feel a "slight delicacy" in giving "O. K." to a message "done up" in this manner, especially from an office that required you, repeatedly, to call for a correct check? And would it not be better for Relay offices to exercise a *little* of the "stubbornness"—right thinking men would not so term it, but allowances must be made for "old women" and "dyspeptics"—complained of, and insist, mildly, *very mildly* insist, at least, humbly request that originating office give a check in accordance with rules for counting? (If a young and inexperienced operator, to point out to him his error and instruct him), thereby avoiding an argument about the check at every relay, and at destination, or the necessity of transmitting a "Kite-tail" to messages, admitting they are in error, know it, but refuse to correct.

If "One in Search of Right" could distinguish between the desire on the part of an operator to have business pass through his hands "O. K." and "stubbornness," the question he refers to you would not be so "vexed" in his locality.

The over-charge scrap-iron-car-load-message (one word. How many of them could Kitchen send a minute) was delivered—"subject to correction."

Respectfully, TAR, PITCH & ROSIN.

PIOUS RAILROAD RESIGNATION RECOMMENDED.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—The article which appeared in the issue of December 15, has developed such a number of Telegraphic Horace Greeley's who show "what they don't know about despatching," that I am constrained to remark that in my opinion, none of them have offered any system or method that will to any considerable extent, facilitate both commercial and railroad business. The examples of orders presented in their communications, cannot by any means be taken as average ones, as any operator who has had experience on a long line can testify. All those who are aware that, in many instances, a single delayed train will necessitate orders to nearly every other train on a Division, all or any of which are liable to be changed, as occasion or progress of the delayed train may require. And when from unavoidable causes, many trains are delayed, it becomes greatly more complicated, and the necessity of utmost exclusive use of the line becomes proportionately greater. The wants of the many are always paramount to those of the few. The plan I would suggest as best calculated to obviate difficulty, and the general delay of outside business, is for dispatchers to put their orders in as concise and brief language as will assure safety, and for operators in general, to cultivate a philosophic and pious resignation, always keeping an ear on the main chance—to get in

SELF-CLOSER.

Mr. E. A. CALLAHAN, Superintendent Gold and Stock Telegraph Company, has resigned, in order to take a leading position in the introduction of the Reporting Telegraph system in Great Britain. It is stated that there are still 4 000 miles of private telegraphs in Great Britain.

WALCOTT, Iowa, March 15, 1872.

To the Editor of the Journal of the Telegraph:

Permit me to express my hearty commendation of the remarks of "D. N. T., Elgin Station," in the JOURNAL of the 15th of February.

The present system gives us many examples similar to his witty "Bobtown," only much worse; moreover, it is highly provocative of profanity.

The "nuisance" is great, and could be easily remedied as "D. N. T." suggests. Very respectfully.

G. E. P.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JAMES D. REID, Editor,
Executive Rooms, Western Union Tel. Co.,
145 Broadway, New York.

NEW YORK, APRIL 1, 1872.

THE WORK OF THE YEAR.

During 1871, the Western Union Telegraph Company purchased over fourteen thousand miles of telegraph wire for the necessities of that year. Already eight thousand miles have been purchased for 1872, and the prospects are that over fifteen thousand miles of wire will be needed to meet the demands of the current year, which come pouring in from all quarters. Some will find it difficult to understand this, and what possible necessity there can exist for it. It is well they should know, although we have alluded fully to it in former years.

To those who have followed the course of the development of the country any explanation will be unnecessary. The railroad extensions of 1871 were over twelve thousand miles. In this item alone may be found the secret of telegraph extension. No road is secure now without a telegraph by its side. How often have we had to say this. The telegraph lines are the leading strings of the locomotive. The iron wire is the angel of the iron horse. So that, forever, they must go together, the gentle leading the strong, just as love rules the world. It is the old story. The rude man succumbs to the gentle woman. It seems poetic, but there is not a bit of poetry about it. It is all gospel, which has been, is now, and shall be, for ever and ever. Amen. So then, find out if you can how many iron roads are being opened up out on the vast territories towards which population is daily pushing. Examine the old railroad routes, how like new shoots on old trees, branches are being flung out on every side, and new arms to distant points are thrust forward to anticipate the march of rival interests. Day and night through all the year, and on both continents, the furnace fires are burning where the iron rail is being too slowly moulded for the orders of the contractor. So long as this lasts, new telegraph lines must be erected, and the orders for both go together.

But to this must be added wires to meet the enlarging demands of business. Every year multiplies the number of those who use the telegraph, and they who habitually u e it, use it more. Even in the face of an invention which bids fair to double the capacity of existing wires, fifteen thousand miles of new wire will be put in use by the Western Union Company before October next. Respecting all this we hope to give some valuable statistics in our next. It will be seen that neglect of the necessities of society, even where its forms are the most primitive and distant, is not a crime chargeable to the Western Union Telegraph Company.

We regret to be obliged to announce the serious illness of our venerable friend, Professor Morse. From the testimony of his physicians, his decease cannot be distant, and may be hourly expected. He has attained to a royal old age, and will depart full of honors. We shall miss his genial face and voice much, for we have loved him. We are glad of having been instrumental in honoring him, and rejoice with the thousands who united with us that the work was done before its subject passed away.

It is stated that a messenger boy connected with the Telegraph Company succeeded in inducing a capitalist to loan him money to invest in Erie, by which, during the recent excitement, he made $1,500. It would, perhaps, be deemed soft were we to commisserate this lad. This boy's success is, no doubt, regarded as a "big thing," which many will feel sorry they did not have pluck to imitate. It is possible that the lad may be wise enough to salt down this easily acquired money, and be content to pursue life hereafter with steady tread, contented with the fruits of honest labor. The chances, however, are against him. The probability is that the slow results of every-day life will not suit him, and that he will ultimately enter the ring of men who live on gambling, if his sudden success does not kill him before the time. The effect of his success on others must be even more pernicious than on himself. There has been too much of this already. We have watched its cursed influence on young men. At one time the condition of our telegraph offices inspired fear of a general debauchment. During the gold excitement of a few years ago, a state of things existed such as caused the utmost anxiety. Bad men found their way into telegraphic ranks, whose chief purpose was to act as confederates of outside parties, and debauch their companions. This great evil, we believe, is now happily removed. We want to see no renewal of it. Yet we shall not be surprised to learn that the success of this lad has caused many to try their hands at the risky game, only to come out of it stripped and corrupted. Stock gambling curses the heart, dries it up, debauches it, makes life a fever, hot, short, unblessed. Better, young men, be poor and pure, than to sell your soul to the stock exchange.

A correspondent asks us to explain the meaning of an *ohm*. We did this service four years ago, but gladly refer to it again.

The term "ohm" is derived from the name of a celebrated electrician, who first ascertained the laws of electrical resistance, and is used to denote a measure of resistance in the same way as an inch, or a yard, is a measure of length. The "ohm," as the unit of resistance, was adopted by a committee of the British Association of Electricians, and is now the acknowledged standard throughout Europe.

Mr. C. F. Varley, before the "ohm" was adopted, established a "unit" by observing the deflection of a galvanometer from a state of neutrality, when the resistance of a single mile of No. 16 copper wire was added to one side of the neutralized circuit. That deflection he designated as the "unit of resistance." The "ohm" is one twenty-fifth of Varley's unit, and, therefore, so much the more delicate. It represents the resistance of about two hundred and ten feet of No. 16 copper wire, or No. 8 galvanized wire, unexposed to disturbing causes, and in a temperature of 60° Fahrenheit.

What are its uses?

The "ohm" measurer is used for testing the resistance of magnet coils, arranging these at a common standard. Magnets of one thousand ohms resistance were detected by this efficient police, which were all but ruining important telegraphic circuits. In Great Britain all wires are tested by it every morning. Their proper condition being known and recorded, any deviation is at once detected. The deviation is expressed in "ohms," and when an operator could not tell by the change in his magnet that any fault existed, this delicate inspector discovers it at once.

It is used also to prove the resistance in batteries, to prevent the source of electric action from being its own chief impediment. It is the aim of all electricians to make the resistance of the battery and of the conductor to correspond, and not have the perfection of the one neutralized by the imperfection of the other.

It is used also in detecting impurities in the wire of magnet coils, and, in doing which, it has been especially useful. It has also compelled such a cutting out of bad joints as has largely redeemed the telegraphic operations of the country from a growing and very formidable source of embarrassment. In aiding the introduction of this instrument, Mr. Varley's visit to America was productive of most beneficent fruitage.

VALUE OF GALVANOMETER TESTS.

In reference to the use of these instruments we have received the following:

Nothing ought to be required to be said now as to the value of galvanometer tests of our wires, and, especially, for the purpose of locating breaks, crosses, escapes, &c.; and yet an occasional reference to actual results may not come amiss. A short time since two wires were found to be crossed nearly all day between stations A. and B. Repairers went over the line, without finding it, and were confident that it was not out of doors; but both A. and B. stoutly maintained that it was not in either of their offices. The cross came in and disappeared several times, and continued until the next day, when X. office tested with his galvanometer, and located the trouble in A. office, and soon after the manager of that office owned up, as follows:

"You have got me this time, sure. But trouble was not in the switch. Some one had thrown a very small piece of fine wire over the switch on to the lightning arresters. The wire was so small that it could not be seen. I discovered that by jarring the

Digitized by Google

switch the cross would come in, and I tested it down to this piece of wire."

Now, a test with the galvanometer at first would have located the difficulty at least twenty-four hours sooner, and saved the valuable time of the wire, besides the lineman's labor. We hope soon to see the galvanometer in constant and general use, and no linemen sent after a trouble, when five minutes' accurate testing would locate the fault within a hundred yards. Let us use brains first, and muscle afterwards.

ARE THE FOOLS ALL DEAD?

This is April Fool's Day, and the question we use as a caption is answered by the coming of the anniversary day, when fooling comes in order, when the juniors, especially, delight in the process of entrapping the seniors into all manner of foolish positions. Yet as this process requires considerable brain, it cannot properly be considered the work of fools.

It is not very safe ground to tread upon, and some may resent the suspicion, yet we venture to ask "are there any fools connected with the Telegraph?" Don't get indignant about it. Let us talk it over.

Do you see that messenger boy? He has a good head. He has a good healthy body. His feet and hands are sound. He has the capital with which many a messenger has sprang to success and honor. But there does not seem much promise there. His hands are brown with dirt, his shoes are slouchy and soiled, he has a piece of tobacco in his mouth, his cap is torn and filthy, he stops on the curb to see every fallen horse, men receive messages from him and sign his book with a kind of detestation. That boy is a fool. He sees no future. He needs a friend to teach him the steps to future honor—to inspire him. The manager might make a man of him. Let him try. It is one of the opportunities of his position. It is a holy duty and delight for goodness to lift up the lowly and the bad.

There is an operator. Look at him. His desk is daubed with ink. His relay is covered with dust. His tariff book is incomplete. He is smoking a dirty meerschaum, and reading the *Sunday Mercury* or the *Police Gazette*. He has charge of an office, and he and the office are alike. His window is unclean, His floor is smudged. He receives customers with his hat on, and his pipe in his mouth. His answers are repellant—his action indifferent. The anxiety of this feeble woman, who is sending a message to her boy, don't disturb him. He is a fool. He don't understand his duty to himself. He don't see what a blessing he could make himself, or how he is lowering a grand business. Won't some one tell him? It might make one fool the less. Don't dismiss him till you try.

There is another fool. He would not take patience to learn his work, gets an idea how letters are made, and thinks he knows all. So he is daily causing mistakes and making them. Precision is unknown to him, deems it talent wasted. So he shuffles his way for awhile, and then comes "John Brown, of Sleepy Hollow, dismissed for incompetency." This class of fools are too numerous. The civil service plan must go in force on such fellows. Put them to a paper machine, and make them write a paragraph of one hundred words with mathematical accuracy. That will bring these slip-shod youths to their marrow.

The biggest fool is the man who comes on our monthly report as "dismissed for drunkenness." We know the name. He is one of the most skilled of operators. He has a good heart, at least has the credit of it. But the smell or the dream of rum makes him hasten to where debauching by rum-selling and rum-drinking is genteel. So he charges himself, fires up, returns to his desk to send the most important of human communications, where fortune or life hangs by a thread, and are now in the hands of a man hot with whiskey. Out with him! Pity stops in such a case outside the office door, and waits until its object reaches the street's fresh air. Hustle the drinkers out, every soul of them. Better yet, never let them come in. We favor a premium to men who enter the service pledged against rum.

Of other fools, more anon.

THE *Handicraft* is a new Scientific Journal which comes to us, bearing upon its face promise of success. It is edited by our good friend Prof. John Phin, well known in connection with the editorship of Scientific Journals in New York, a fluent writer and thoroughly posted. We wish *Handicraft* abundant success, and we expect to scissor it freely.

From Chicago we have the following inquiry:

How many words are there in the following message:

"Buy five hundred New York Central stock."

We answer that there are seven.

NEW INVENTION.

The Girard (Pa.) *Cosmopolite* says that, at a certain station on the Philadelphia and Erie Railroad, the company has a new night telegraph operator who, if inclined to slumber, is too ingeniously wide-awake to be caught napping at his post. Recently he was seized with drowsiness, which he could not shake off. As it was his duty to report all passing he dared not yield, and yet could not resist. Necessity at length suggested an alarm signal, which he proceeded to put in operation, by suspending a scuttle full of coal by means of a cord which was passed through the key-hole of his office door, and fastened across the track at the requisite elevation. He then resigned himself to rosy dreams, which were interrupted by a passing train, the engine of which snapped the cord, causing the coal scuttle to come down with a noise that effectually roused him to his duty.

ALL hail to electricity! Not content with the blessing it has already conferred upon the world, it has achieved a new triumph. Already employed to restore vigor to the gouty limbs of decrepit *bon vivants*, a French physician has recently shown that electricity is an efficient remedy for the evil effects of drinking on the human nose. Doctor Bernier claims that by the application of an electric current to noses even of the most bacchanalian hue, the flesh may be made "to become again as the flesh of a little child;" and he supports his assertion by a cure performed on the proboscis of a patient of his own, a woman (let it be told in a whisper); and not only that, but one of high rank. A pocket battery will prove as great a necessity, and almost as valuable as a pocket book; and no longer need the tippler of high rank or low degree carry a lighthouse about with him, or bear an appendage that has no faint resemblance to the last or the first "rose of Summer."

LONDON SOCIETY OF ARTS.

This Society, after discussing the question of the purchase by Government of the great ocean cables, have published a report, much of which is without special significance, which concludes as follows:

"It is confidently submitted that the measure proposed, which is doubtless one of easier accomplishment than that of the purchase of the inland telegraphs of trading companies, commends itself to the immediate and special support of those engaged in the Arts, Manufactures, and Commerce of our colonies, of our Indian possessions, and of the American continent, for the removal of the existing clogs, and for the prevention of increased clogs of expense, particularly in competition with the advanced administrative arrangements on this subject of the Continental States."

By order of the Council.

P. LE NEVE FOSTER, Secretary.

A FEW years ago, at the time of the completion of the telegraphic line to the Mountain House, for a few days strong winds prevailed, causing that peculiarly loud humming noise of the wires under such circumstances. At length the wind died away, and the telegraphic Æolian harp was mute. Several days thereafter, the proprietor of the Mountain House, on his way to Catskill, reined up in front of the Half Way House to water his horses, when he was accosted by the Kiskatom landlord: "How's things on the mountain?" "Lively," was the response. "Ain't doin' much telegraphin', are you?" "O, yes; the line is quite well patronized." "Well, I didn't think so; *I ain't heerd a dispatch go up in three or four days.*"—*Catskill Recorder.*

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY.
145 Broadway, New York,
April 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since March 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

428 Aullville, Mo.
151 Beaver Station, Pa.
298 Beecher, Ill.
246 Cartersville, Ga., re-opened.
418 DeWitt, Mo.
210 Elba, Lapeer Co., Mich.
348 Edwardsville Crossing, Ill., re-opened.
14 Freeport, Me., ck. Brunswick, Me. Heretofore an Other Line office.
41 Fanwood, N. J., ck. Plainfield, N. J.
298 Grant, Kankakee Co., Ill.
76 Goldsboro', York Co., Pa.
52 Greenbrook, N. J., check Bound Brook, N. J.
308 Hoopston, Ill.
308 Lovejoy, Iroquois Co., Ill.
298 Momence, Ill.
32 Norfolk, Conn.
298 Papineau, Ill.
21 Somerville, Mass.
338 Tilden, Ill.
211 Waltz, Mich.
281 Whitestown, Ind.

OFFICES CLOSED.

Armstrong Run, Pa.; Nameoki, Ill., and Natasulga, Ala.

GENERAL INFORMATION.

The name of the office heretofore known as Pile Falls, Pa., has been changed to Falls City, Pa.; that of Spruce Run, N. J., changed to Glen Gardner, N. J., and that of New Market, N. J., changed to Dun Ellen, N. J.

Business for Dun Ellen, N. J., should be checked to Plainfield, N. J.

The following offices will hereafter be checked direct: Abington, Montgomery Co. Pa.; Cranford, N. J.; Pomona, N. J., and Glen Gardner, N. J.

The P. O. address of Washington, R. I., is Coventry, R. I., and of Abington, Montgomery Co., Pa., Waverly Heights, Pa.

The Western Union office at Tionesta, Pa., has been again re-opened. Business will therefore be checked direct.

OFFICES HAVING "SPECIAL SHEET A,"

Will hereafter use their "special rate" to Brunswick, Me., for tariff to Freeport, Me., and check Fair Haven, Conn., same as "special rate" to New Haven, Conn.

WILLIAM ORTON, Pres't.

Digitized by Google

TELEGRAPHERS' MUTUAL LIFE INSURANCE.

At the special meeting called to elect a new Treasurer on the 21st instant, there was an unusually large attendance, and Mr. A. S. Brown was unanimously elected Treasurer from April 1. This is an election eminently fit to be made, and is the greatest assurance which could be given of success.

We regret that the unusual pressure upon Mr. Applebaugh and ourself, caused by the recent deaths of which we now make mention, prevents the publication of the large list of receipts which will appear in our next issue. We will at that time give a complete statement of the condition of the Association.

DEATH OF JOHN GRANT.

Death is reaping his usual spring harvest. We have to announce the death by consumption of Mr. John Grant, formerly manager of the Guelph, Ontario, Montreal Telegraph Company's office, at Atlanta, Ga., where he had gone to make a last effort to recover his health. He died March 3d, and was buried in Guelph March 10th. He leaves a wife and two children. We only received notice of Mr. Grant's decease March 19th, from Mr. James Bryce, Manager, Guelph. This calls for

ASSESSMENT No. 28

on all certificates up to 1447, inclusive, and the call will be regarded as issued April 1, 1872.

MISS E. SAMMIS.

It is with heartfelt sorrow that we record the death of one of the truest and noblest of women, Miss E. Sammis, of Quarantine Station, Staten Island, who died March 24th, at Williamsburg, of tumor in the throat, causing death by strangulation. One week before her death she wrote the following note to the Secretary. Every dollar she ever sent to us was accompanied by just such words of cheerfulness and gratitude. Many will remember them, for we published several. Poor girl! she did her duty nobly and well. She is now in God's good care. The day of toil is over, and she rests evermore. She is the first of the Sisters of the Association who has died.

W. K. APPLEBAUGH, ESQ., *Secretary.*

Enclosed please find two dollars to meet assessments numbers 26 and 27. Death is dealing his blows silently but surely all around us. Let us be thankful for the means of relief and comfort which a connection with our Association affords, and gladly and quickly as our means permit respond to these Heart Calls. Very truly yours,

E. SAMMIS.

BROOKLYN, March 17, 1872.

We have received the following from one who knew Miss Sammis well:

NEW YORK, March 26th, 1872.

J. D. REID, ESQ.:

Dear Sir:—I have just heard of the death of Miss Emma Sammis, Manager of the telegraph office at Quarantine, Staten Island.

From my long acquaintance with her I cannot refrain from saying a few words in regard to her now that she has passed away.

She commenced telegraphing at Hicksville, Long Island, more for amusement than profit, the family being then in good circumstances, about 1856 or '57. They were, however, burned out a few years after, and the loss was so heavy that they were obliged to give up their little property, and the support of the family, in a great measure, through the infirmities of her father, devolved upon this daughter. She has attended to her arduous duties cheerfully, unflinchingly, and faithfully.

She was always happy in her religious convictions; relying most implicitly in the Saviors' promise to all who should trust in him. She was as guileless as she was sincere, and she has entered into and is now enjoying her reward. W.

This will call for

ASSESSMENT No. 29,

and we trust will be the last for some time to come. We hope it will be met all the more promptly, because of the fact, that Miss Sammis was the first of the sisterhood to fall from the ranks.

SAN FRANCISCO, February 15, 1872.

NEW MATERIAL FOR TELEGRAPHIC USE.—Our correspondent at Camptonville writes: "During the recent heavy blow in the mountains the telegraph lines in the neighborhood of Camptonville were sadly demoralized and strewn over the country in rather a mixed manner. A good friend of the operator, probably a miner, willing to aid in putting things to rights, voluntarily repaired the line in his neighborhood. Having no wire, he used the next best material he could find, which happened to be a piece of fuse. With this he made a very artistic connection, leaving the line, in appearance as good as ever. Unfortunately it wouldn't work. The repairers from town traversed the line from office to office and pronounced it O. K. Still no current. The repairers started again, wallowing through the snow, blessing their luck and the line, and closely scanning each joint. The fuse was found, cut out, and communication restored. The operator prays now 'deliver me from my friends.' Head office says, 'gross negligence on your part Mr. De Biz.' Our mining friend is convinced now that fuse won't always work. 'Dog on 'em,' they put in powerful weak powder."

The following is old, but has not appeared in the JOURNAL:

TICK-LISH TELEGRAPHING.—Two young men, telegraph operators, boarding at one of our leading third-class hotels, find great amusement in carrying on conversation with each other at the table by ticking on their plates with knife, fork, or spoon. A combination of sounds or ticks constitutes the telegraphic alphabet, and persons familiar with these sounds can converse thereby as intelligently as with spoken words. A few days ago, while these fun-loving youths were seated at breakfast, a stout-built young man entered the dining room with a handsome girl on his arm, whose blushing countenance showed her to be a bride. The couple had, in fact, been married but a day or two previous, and had come to San Francisco from their home in Oakland, or Mud Springs, or some other rural village, for the purpose of spending the honeymoon. The telegraphic tickers commenced as soon as the husband and wife had seated themselves.

No. 1 opened the discourse as follows: "What a lovely pigeon this is alongside of me—ain't she?"

No. 2.—"Perfectly charming—looks as if butter would not melt in her mouth. Just married, I guess? Don't you think so?"

No. 1.—"Yes, I should judge she was. What luscious lips she's got! If that country bumpkin beside her was out of the road, I'd give her a hug and a kiss just for luck."

No. 2.—"Suppose you try it, anyhow. Give her a little nudge under the table with your knee."

There is no telling to what extent the impudent rascals might have gone, but for an amazing and entirely unforeseen event. The bridegroom's face had flushed, and a dark scowl was on his brow during the progress of the ticking conversation; but the operators were too much occupied with each other to pay any attention to him. The reader may form some idea of the young men's consternation when the partner of the lady picked up his knife, and ticked off the following terse but vigorous message: "This lady is my wife, and as soon as she gets through with her breakfast, I propose to wring both your necks, you insolent whelps." The bridegroom was a telegraph operator, and "knew how it was himself."—*San Francisco Chronicle.*

THE SONG OF THE POLES.

MACKINAW, Ill., March 11, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—In the JOURNAL of March 1, I notice a question asked by "Young Operator," relative to the cause of the humming noise of the line at telegraph poles, &c. I also notice that your answer is "Simply vibration of the wire, caused by winds, &c."

If this noise is occasioned by winds, why is it that the greatest noise occurs during still clear sharp cold nights during winter, and that during the hardest winds there is no noise at all? For instance, yesterday the wind blew from the North—our line runs East and West, and there was no noise perceptible. Think you are mistaken in the matter. I notice that from one to three days before a storm, this humming noise commences, and is kept up until the atmosphere changes, when the noise ceases. Is it not the action of the electricity of the atmosphere on that of the line, that causes it? I would also like to ask if there is any remedy or invention that will stop this noise, where the line is fastened to the house; a common insulator will not do it. I also notice that where loop wires are run into an office, through tubes, that the noise is greater than when gutta-percha covered wire is used, and simply run through holes and wedged with pins.

Respectfully &c., OLD OPERATOR.

If "Old Operator" will take an œlian harp, such as are placed under the sash of a window, he will find that drawing the strings tight will destroy the sound. Heavy winds do this with the wire. The wire responds to the action of remote storms upon it, just as men working upon the wire can be heard at any office many miles distant. Compartively moderate winds produce the sounds heard at telegraph poles and windows. The sounds can be stopped altogether by resting the wire on gutta percha, or any elastic substance.

KIND WORDS.

CHARLOTTE, N. C. Feb. 26, 1872.

To the Editor of the Journal of the Telegraph:

Dear Sir:—I regret to see it announced that you have determined to sever your connection with the JOURNAL OF THE TELEGRAPH. I have not, it is true, had the pleasure of meeting you personally, but judging from your "thoughts on paper," your words of cheer and encouragement, your endeavor to raise the morals of the profession to a higher standard, to make duty a pleasure, words and efforts that have not been in vain.

With my best wishes for your future welfare and happiness, I am, yours, G. H. KING, Manager.

BOSTON, February 27th.

To the Editor of the Journal of the Telegraph:

The many friends of Mr. J. Perley Munroe, of Concord, N. H., for three years past, night report operator, at Worcester, Mass., will be pleased to learn of his appointment as City Editor of the *Worcester Daily Spy.* Mr. Munroe entered upon his new position, March 1st, his Telegraphic Mantle falling upon Mr. P. L. Ryder, whose promotion to the position lately filled by M. Munroe is a merited recognition of three years faithful services in the Worcester Office. By the resignation of Mr. Munroe, one of the best operators and truest *men* in the fraternity is lost to the Telegraph service. BOSTONIA.

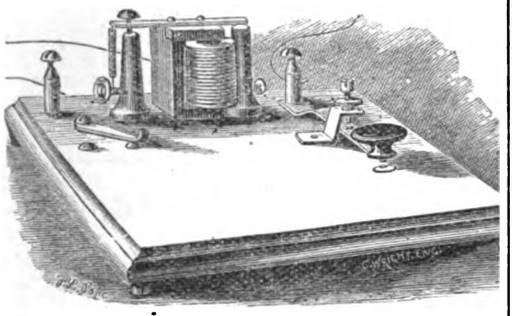
MARRIED.

SHULTZ—KILLIAN.—On Thursday evening, March 14th, 1872, in Elizabethtown, Pa., by the Rev. F. W. Weiskotten, H. T. Shultz, Manager P. R. R. & W. U. Telegraph Office, Elizabethtown, Pa., to Fianna Killian, of the same place.

MILLER—MANCHESTER.—At Charles City, Iowa, Monday evening, March 4th, 1872, Mr, Edward O. Miller, of St Ausgar, Iowa, Express operator W. U. Telegraph Co., to Miss Nettie E. Manchester, of Osage, Iowa.

BORN.

BUSH.—To W. T. Bush, Manager W. U. Telegraph Office, Franklin, Louisana, February 23d, a Son, weighing ten pounds.



Digitized by Google

To Make a Cheap Microscope.—Take a slip of thick paper or card-board, and punch a small round hole in it, not larger than an ordinary slate pencil. (The paper must be firm and even, and the hole truly circular, with a smooth edge all around, to ensure success. The cover of a small pill-box will do very nicely, as in using it the rim will help to exclude the extraneous light.) Then take a drop of the purest water on the end of a pencil and insert it carefully in the hole of the paper, and withdraw the pencil as gently as possible, leaving the drop of water in the hole. The water should not be allowed to spread the least over the surface of the paper; it will then assume the shape of a double-convex lens, and if properly constructed it may have a magnifying power of 20 or 30 times. To use it, it should be held as close to the eye as possible, and the object to be viewed brought quite close to the lens; the proper focal distance will soon be ascertained. The hole must not be made too large, or the weight of the water will destroy its lenticular form; for the same reason and to prevent too great convexity, the quantity of water must be limited; while too small a quantity will not give a sufficient magnifying power.

Electricity and Altitude.—M. Matteucci has found that if the surface of the earth at different altitudes be connected by a conductor, a constant current of electricity will flow from the lower to the higher point; the intensity of the current increasing with the difference of the altitudes. Thus, between Florence and Turin the deflection of the galvanometer from the current passing through it was from 15 to 20 degrees; between Pontedera and Volterra, from 20 to 25; and between Aoste and Courmayeur, from 40 to 50. Atmospheric changes, however, modify, of course, the effects, as do also diversities of latitude and geological formation. The aurora borealis and the variations of terrestrial magnetism are supposed to have an intimate relation with this distribution of electrical conditions.

THE NONPAREIL TELEGRAPH APPARATUS.

(Patent applied for.)

This apparatus supplies a want which has long been felt, viz.: that of a SIMPLE and CHEAP

MORSE TELEGRAPHIC INSTRUMENT,

with all the necessary Batteries and other appurtenances in a CONVENIENT and COMPACT form.

By means of a switch, which is now placed on each instrument, they can be worked as desired, either as the open or the ordinary continuous, or closed circuits.

It is intended especially for the use of

STUDENTS, AMATEURS, AND OPERATORS,

but will be found to be equally well adapted for use on

PRIVATE TELEGRAPH LINES,

or Short Lines of any description, which are not over three or four miles in length.

A NEW FORM OF BATTERY

is employed, which is compact, efficient, and economical, and especially adapted to the purpose for which it was designed. Each instrument will be accompanied by a

BATTERY, CHEMICALS, INSULATED WIRE

for connections, together with an

ILLUSTRATED BOOK OF INSTRUCTIONS,

which in itself forms a complete elementary treatise upon the ART OF TELEGRAPHY.

PRICES:

Single Instrument, complete, with Batteries, etc.....$8 00
Two Instruments, " " " " 15 00

Sent by Express on receipt of price.

Remittances may be made by Post Office Order, Registered Letter, or Draft payable to our order. Persons ordering Instruments will please write plainly, giving Post Office, County, and State, with instructions for shipment. Address,

F. L. POPE & CO.,
P. O. Box 6010. 80 Broadway, (Room 51,) New York.

The Nonpareil Telegraph Apparatus may be procured through the leading dealers in Telegraph Supplies throughout the country.

☞ SEND FOR A CIRCULAR. ☜

16,000 MILES

OF

"JOHNSON'S" WIRE

USED BY THE

TELEGRAPHS OF THE UNITED STATES

DURING THE YEAR 1871.

This is sufficient refutation of all the intimations thrown out by the Manufacturers and Importers of other Wires, reflecting upon the acknowledged superiority of the Wire manufactured by

Messrs. RICHARD JOHNSON & NEPHEW,

MANCHESTER, ENGLAND.

Their Works are the Largest in the World.

The great advantage which they possess over other manufacturers is their patent process of drawing Wire in great lengths (averaging 1,200 feet).

All Telegraphers know that, in nine cases out of ten, breaks in Wire occur at joints, hence the less joints the fewer breaks.

Messrs. Richard Johnson & Nephew furnish three-fourths of all the Telegraph Wire used by the

ENGLISH GOVERNMENT.

This Wire is necessarily subject to the tests, etc., imposed by the English Post-office Department.

A large stock always on hand and for sale at the lowest market prices—both free and in bond.

AMERICAN FIRE ALARM

AND

POLICE TELEGRAPH.

GAMEWELL & CO., Proprietors,

NO. 104 CENTRE STREET, NEW YORK.

J. W. STOVER,
General Agent and Superintendent.

L. B. FIRMAN, Chicago, Ill.,
General Agent for the West and North West.

J. R. DOWELL, Richmond, Va.,
Special Agent for Virginia and North Carolina.

J. A. BRENNER, Augusta, Ga.,
Special Agent for Georgia and South Carolina.

L. M. MONROE, New Canaan, Conn.,
Special Agent for New England.

This system of Fire Alarm and Police Telegraph, with a Central office, or upon the

AUTOMATIC PLAN,

is now in operation in the following cities, to which reference is made for evidence of its great SUPERIORITY, VALUE and UNIFORM reliability:

Albany, N Y.,	New Orleans, La.,
Alleghany, Pa.,	New Haven, Conn.,
Boston, Mass.,	Newark, N. J.,
Buffalo, N. Y.,	Omaha, Neb.,
Baltimore, Md.,	Philadelphia, Pa.,
Chicago, Ill.,	Pittsburg, Pa.,
Cincinnati, Ohio,	Portland, Me.,
Columbus, Ohio,	Peoria, Ill.,
Cambridge, Mass.,	Providence, R. I.,
Charlestown, Mass.,	Quebec, L. C.,
Covington, Ky.,	Rochester, N. Y.,
Detroit, Mich.,	Richmond, Va.,
Dayton, Ohio,	Indianapolis, Ind.,
Elizabeth, N. J.,	St. Louis, Mo.,
Fall River, Mass.,	St. John, N. B.,
Fitchburg, Mass.,	Springfield, Mass.,
Hartford, Conn.,	San Francisco, Cal.,
Jersey City, N. J.,	Savannah, Ga.,
Louisville, Ky.,	Syracuse, N. Y.,
Lawrence, Mass.,	Troy, N. Y.,
Mobile, Ala.,	Toledo, Ohio,
Montreal, Canada,	Toronto, Canada,
Milwaukee, Wis.,	Washington, D. C.,
New York City,	Worcester, Mass.,
Lynn, Mass.,	New Bedford, Mass.,
Lowell, Mass.,	Bridgeport, Conn.

The distinctive features of these systems of

FIRE ALARM AND POLICE TELEGRAPHS,

ARE,

First—The Automatic Signal Boxes, the simple electro-mechanism of which enables any one—even a child—to give an *instantaneous, general,* and *definite* alarm of fire.

Second—The Automatic Repeater, through which the apparatus may be distributed in a combination of circuits, and the entire system successfully worked without the constant personal attention of either operators or watchmen.

Third—The Electro-Mechanical Bell Strikers, adapted to produce the full tone of the largest church or tower bells.

Fourth—The Electro-Mechanical Gong Striker, for hose and engine houses, by means of which the location of the fire is instantaneously communicated to the members of each fire company.

These features combined form the

ONLY PERFECT, COMPLETE, AND RELIABLE SYSTEM

OF

FIRE ALARM TELEGRAPH IN THE WORLD.

Messrs. GAMEWELL & CO. are the owners of the original *FARMER AND CHANNING PATENTS,* one of the most important of which has just been extended for seven years. During the past seventeen years they have spared no expense or effort to secure improvements, and the systems are now covered by

MORE THAN TWENTY PATENTS.

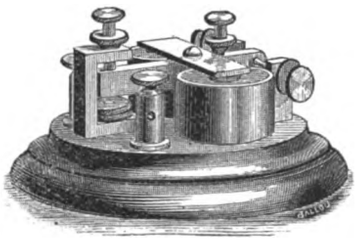
The introduction and operation of the

AUTOMATIC SYSTEM

involves so little expense, compared to the benefit which it confers, that even small communities can profitably adopt and maintain it.

The co-operation of TELEGRAPHERS in securing its introduction into their localities is cordially invited, and their efforts will be duly appreciated and compensated.

Any information desired in regard to the above system will be cheerfully and promptly furnished upon application at the office.



A pamphlet setting forth more fully its advantages and superiority, has been printed, and will be supplied to Municipal Authorities and others interested in Fire Alarm and Police Telegraphy upon application as above.

MECHANICAL TELEGRAPH INSTRUMENT

PATENTED MAY 31st, 1870.

For Students, Colleges, &c. No battery required. An ordinary key and sounder is placed upon a proper base. The sounder is moved by a lever under the base, connected with the key, making a perfect instrument for those wishing to learn the Art of Telegraphy. An expert could not tell, without examining it, that the instrument was not worked by a battery.

It should be introduced into every school and family where there are those who wish to learn the Art.

Hundreds of persons throughout the country desire to become expert Telegraphists, and are constantly seeking permission to practice in the various telegraph offices.

This instrument is an outgrowth of this pressing demand. The Inventor is himself a practical operator, now in active service. Operators and others wishing to teach or learn the Art, will be delighted with this instrument.

It can be placed anywhere, as it does not occupy a space more than six inches square.

Its cost is but $7, and there is no expense whatever to keep it constantly in working order.

We will send a copy of SMITH'S MANUAL, free of charge, with each instrument, to individuals or clubs. The instructions in this Manual are particularly adapted to those who wish to learn by sound.

Special and liberal terms to manufacturers.

Remittances can be made by certified draft on New York, Cleveland, or Pittsburgh, money by express, charges paid, post office order, or registered letter at our risk.

Parties ordering instruments, from points except well-known cities, will please give the name of county and State.

Price, $7. Silver Plated, Extra Finish, $10.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 10. NEW YORK, APRIL 15, 1872. WHOLE NO. 107.

MORSE.

"What hath God wrought?"

As like the setting sun, and darkness gathers round,
All nature sinks in sweet repose and rest;
So thy frail body sinks in hallowed ground.
The Genius of the Age, by all confessed.

Oh, wondrous mind! Oh, man of patience rare!
Hope, in fruition sweet, o'erwhelmed thy fears,
And nations placed their honors on thy brow,
And seek thy tomb with heavy hearts and tears.

"What hath God wrought?" For thee, O Morse, a name
That evermore, throughout all time, shall stand;
The burden of thy gifts, on scrolls of Fame,
Shall live forever, and in every land.

April 5, 1872. HENRY C. COOPER.

DEATH OF PROFESSOR MORSE.

As we feared, when our last issue went to press, the good old man whose presence often hallowed our work, has passed away. Professor Morse died at 8 P. M., Tuesday, April 2d, at his residence, No. 5 West 22d Street, New York. The particulars connected with his last illness which are of any interest are so tenderly introduced in the funeral address of Mr. Morse's pastor, Dr. William Adams, which we publish in full, that we make no other reference thereto. His death was beautiful in its sweet serenity, in its heavenly peace, in its unclouded vision. Even in the state of apparent unconsciousness there were not lacking evidence, that the intellect retained its life royally to the close. We trust no one who receives this paper will lay it aside until the touching address of Dr. Adams is read. We only wish that there could be transferred to the printed lines the deep pathos, the voice in which the heart was so regnant as to make articulation occasionally uncertain and tremulous, and the fine dignified form of the reverend mourner as he uttered these last words of sacred affection over the body of the man he loved.

It seems unnecessary for us to recapitulate the facts of Mr. Morse's life and yet it seems a fitting time to refer briefly to them.

April 27, 1791, within sight of Bunker Hill, Samuel Finley Breese Morse was born. He was the son of Rev. Jedediah Morse, D. D., author of that many-volumed series of text books from which the passing generation studied geography. His historical works, also, are numerous. He was a graduate of Yale, 1783, and it was to Yale that he sent the boy Samuel, who graduated thence in 1810, in company with Gov. Ellsworth of Connecticut, President Hasbrouck of Rutgers, Prof. Chauncey A. Goodrich, Prof. Ebenezer Kellogg and other distinguished men. His first bent was toward engineering, but immediately after graduation he decided upon the life of an artist; so went to England with Washington Allston in 1811, becoming then a pupil of Benjamin West.

In 1818 he exhibited at the Royal Academy his "Dying Hercules," and in May of that year a plaster model of the same which he had made in preparing for the picture, won the gold medal of the London Adelphia Society of Arts. This success encouraged him to compete for the premium for historical composition. The picture painted for this purpose was "The Judgment of Jupiter," between Apolla, Marpessa, and Idas; and West is authority for saying that it would have won the prize had not his departure from England withdrawn it from competition under the rules. In 1819, he returned, settling in Boston, afterward going to New Hampshire and getting $15 the head for portraits. Thence at the solicitation of friends in 1822, he came to New York. The city of New York gave him a commission for a full-length likeness of Lafayette, and orders poured in. In 1826 the National Academy of Design was formed, growing out of a drawing association started in 1824, Mr. Morse taking an active part in the organization, and being elected its first president. This position he held for sixteen years. The first course of art lectures delivered in America was before the New York Athenæum. One of his important paintings is a large picture of the House of Representatives of that day, with numerous portraits.

In 1829 he started again for Europe, staying three years. While in Paris he painted a picture of one of the Louvre galleries, copying the chiefly notable paintings on the walls in miniature. His election to the chair of the Literature of the Arts of Design in the University of New York recalled him, and in October, 1832, he sailed from Havre in the packet ship Sully. There was the birthplace of the Morse electric telegraph.

At college he had devoted much time to the study of chemistry, under the supervision of Professor Silliman, and even in after years the phenomena of electricity, and of electro-magnetism had been to him a source of considerable speculation, and had been the source of frequent conversation with his friend Professor J. F. Dana. During the present voyage from Havre to New York, the conversation turned accidentally on this subject, in connection with a discovery that had shortly before been made in France, of the corelation of electricity and magnetism.

During all the years of his artist life he had retained his early love for science, and usually kept himself well informed of its progress. Hence he eagerly entered into the conversation which thus sprang up.

"Why," said he, "if that is so, and the presence of electricity could be made visible in any desired part of the circuit, I see no reason why intelligence might not be transmitted instantaneously by electricity."

"How convenient it would be," added one of the passengers, "if we could send news in that manner."

"Why can't we?" asked Morse, fascinated with the idea.

From that time the subject occupied his thoughts, and he began forthwith to exercise his Yankee ingenuity in devising the requisite apparatus. It is stated by a distinguished biographer that "before the Sully dropped her anchor in New York harbor, he had invented and put on paper, in drawings and explanatory words, the chief features of the apparatus employed, to this hour, by far the greater number of telegraph lines of the world. The system of dots and lines, the narrow ribbon of paper upon a revolving block, and a mode of burying wires in the earth all were thought of and recorded on board of the packet ship. Except the idea of suspending the wire on posts, the essential devices of the invention were completed on that vessel. A few days after landing the plan of supporting the wires on posts was thought of, though he still preferred his original conception of the buried tubes. Science had before Morse done her part. It remained for the inventor to devise an apparatus which would utilize scientific truth, and Samuel Morse was the man."

Of course the invention of the telegraph was, like all the greatest things, in some measure a growth, but the world has recognized Prof. Morse as at least the contributor of the greatest share of the origination, and the one successful promoter of its realization. His first idea was to pass a strip of chemically prepared paper in contact with the wire, decomposing the chemicals so as to form marks of different lengths which should form a sign alphabet. Next he thought of the action of electricity upon a lever as a mode of using pens and ink, but this he abandoned for the indenting steel point on the end of a lever which is now in use. In 1835 he completed a rude apparatus, all made by himself, with an experimental wire of half a mile around a room, but this only transmitted in one direction. By 1837 he had ready an improved apparatus, which he exhibited at one of the rooms in the University. This year he went to Washington, filed his caveat, and asked for a Congressional appropriation for a line thence to Baltimore. The session passed without action, and he went abroad. England refused him a patent, Wheatstone having in the meantime got to work; in France he obtained a *brevet d'invention*. But he met with little encouragement abroad, and came back to struggle through poverty and ridicule for four long years. Session after session he persevered. His bill was amended by Congressional wits to include experiments in mesmerism and *Millerism*, the chair refusing to rule out the absurd amendment on the plea that "it would require a scientific analysis to determine how far the magnetism of mesmerism was analogous to that to be employed in the telegraphs." At last came the close of the session of '43. On the evening of March 3, the Professor gave up all hope of immediate success in Congress, and returned to his hotel, to start for New York the next day. "At the midnight hour of the expiring session," by a vote of 89 to 83, the bill was passed, and in the morning the inventor knew the dawn which follows the darkest hour.

Digitized by Google

In reference to this period we clip the following from *Harper's Monthly* of January, 1862:

During the entire last day of the session Mr. Morse watched the course of legislation from the gallery with an anxiety probably shared by few of the eager expectants who, from their places in the gallery above, hung with anxious solicitude upon the action of the measures in which they were especially interested upon the floor of the Senate. At lenght, worn out by the interminable discussion of some Senator who seemed to be speaking against time, and overcome by his prolonged watching, he left the gallery at a late hour and returned to his lodgings, under the belief that it was not possible his bill could be reached, and that he must again turn his attention to those labors of the brush and easel by means of which he might be enabled to prosecute appeals to Congress at a future time.

He accordingly made his preparations to return to New York on the following morning, and retiring to rest, sank into a profound slumber, from which he did not awake until a late hour on the following morning. But a short time after, while seated at the breakfast-table, the servant announced that a lady desired to see him. Upon entering the parlor he encountered Miss Annie Ellsworth, the daughter of the Commissioner of Patents, whose face was all aglow with pleasure.

"I have come to congratulate you," she remarked, as he entered the room, and approached to shake hands with her.

"To congratulate me!" replied Mr. Morse, "and for what?"

"Why, upon the passage of your bill, to be sure," she replied.

"You must surely be mistaken; for I left at a late hour, and its fate seemed inevitable."

"Indeed, I am not mistaken," she rejoined; "father remained until the close of the session, and your bill was the very last that was acted on, and I begged permission to convey to you the news. I am so happy that I am the first to tell you."

The feelings of Mr. Morse may be better imagined than described. He grasped his young companion warmly by the hand and thanked her over and over again for the joyful intelligence. "As a reward," concluded he, "for being the first bearer of the news, you shall send over the telegraph the first message it conveys."

"I will hold you to that promise," replied she. "Remember."

"Remember," responded Mr. Morse; and they parted.

By the month of May, 1844, the whole line was laid, and magnets and recording instruments were attached to the ends of the wires at Mount Clare Depot, Baltimore, and at the Supreme Court Chamber, in the Capitol at Washington. When the circuit was complete, and the signal at the one end of the line was responded to by the operator at the other, Mr. Morse sent a messenger to Miss Ellsworth to inform her that the telegraph awaited her message. She speedily responded to this, and sent for transmission the following, which was the first formal dispatch ever sent through a telegraphic wire connecting remote places with each other:

"WHAT HATH GOD WROUGHT!"

The original of the message is now in the archives of the Historical Society at Hartford, Connecticut.

In 1842 the first submarine cable was laid by him—across New York harbor—winning the gold medal of the American Institute. Mr. Morse's letter to the Secretary of the Treasury, 10th of August, 1843, contained the first suggestion of the Atlantic telegraph. Honors were poured in upon him. In 1851 a convention to select a uniform system for all Germany, adopted his; in 1857 the representatives of the chief European powers, assembled at Paris, presented him with 400,000 francs on account of his invention. Yale made him a doctor of laws. France enrolled him in her Legion of Honor. Austria, the German States, Denmark, Turkey, gave him their highest honors. His fame followed the wires till the globe was girdled.

He has also been the recipient of honorary banquets in London, Paris and in this city. One of the latest honors paid to him was the erection of his statue in Central Park, last Summer. At that time delegates from the telegraphic fraternity of the entire country assembled in this city, to do honor to the man who had done so much for his race. Dispatches were received from Calcutta, from San Francisco, and from hundreds of other intermediate places, all uniting in the general strain of thanks and gratulation. On the 22d of last February he was selected as the fittest one to unveil the statue of Franklin in Printing House-Square, after which time he was very rarely seen in public. Prof. Morse was twice married; and his private life was one of almost unalloyed happiness. He resided during the Summer at Poughkeepsie, in a delightful country-house on the banks of the Hudson, surrounded by everything that could minister to his comfort or gratify his tastes. In the winter he generally lived in New York. By those who have examined into the question, it is reported that the first idea of a sub-marine cable to Europe emanated in the brain of Prof. Morse, in which case there is little connected with telegraphy of which he may not be said to be the author.

Mr. Morse, after a life of great activity, intermixed with no little personal annoyance and many pleasant remembrances, at the age of seventy, retired from the active duties of life, and devoted himself to the gratification of the tastes of a cultivated gentleman, and the exercise of a generous hospitality. His country residence, situated in a most picturesque spot, amidst deep ravines and lofty forest trees, upon the banks of the Hudson, a short distance from the town of Poughkeepsie, is built in the Italian style of villa architecture, and contains a high tower, and extensive piazzas clustering with vines and flowers.

In this delightful spot, adorned with all the chasteness of an artist's taste, in the midst of a charming and affectionate family, and a large circle of sympathizing friends, the evening of his life was largely passed in quiet and undisturbed repose. Occasionally the little world of "Locust Grove" was fluttered by the announcement of the completion of some new telegraphic enterprise, as the fruits of his invention, but it soon subsided into its customary channel, and moved along as quietly and as undisturbed as the dreamy river that flowed languidly at its feet.

His city home was as beautiful as a refined taste and ample fortune could make it. He leaves his family amply provided as to means, and the richer legacy of his own memory.

PROF. MORSE'S FUNERAL.

The funeral services in honor of Prof. Morse were held Friday, April 5th, at Madison Square Presbyterian Church, New York, preceded by a prayer at the house in West Twenty-second street, where only the relatives and intimate friends were in attendance. All the available space in the Church, excepting reserved pews along the center aisle, was crowded an hour before the time appointed for the services. The communion table was covered with the choicest flowers arranged as crosses, crowns, and wreaths, one beautiful cross of rare, white blossoms, being a tribute from the young ladies of Rutgers College.

The body was inclosed in a plain casket, covered with a black cloth with a narrow beading of silver running around it. It was covered with a pall of black velvet, upon which were, at the head, a crown surmounted by a cross of flowers, while an anchor rested near the centre of the coffin, and a wreath at the foot, while the table in front of the pulpit was covered with floral offerings.

At 11 o'clock the funeral procession entered the Church in the following order during the rendering of an original offertory of dirge music by the organist, Mr. Bassford:

Rev. Wm. Adams, D. D.;

Rev. Francis B. Wheeler, of Poughkeepsie, Pastor of the Church which Professor Morse attended when at Poughkeepsie.

Corpse.

Pall Bearers:

William Orton,	Cyrus W. Field,
Daniel Huntington,	Charles Butler,
Peter Cooper,	John A. Dix,
Cambridge Livingston,	Ezra Cornell.

The family.

Governor Hoffman and Staff.

Members of the Legislature.

Directors of the New York, Newfoundland and London Telegraph Company.

Directors of the Western Union Telegraph Company and officers and operators.

Members of the Academy of Design.

Members of the Evangelical Alliance.

Members of the Chamber of Commerce.

Members of the Association for the Advancement of Science and Art.

Members of the New York Stock Exchange.

Delegations from the Common Councils of New York, Brooklyn, and Poughkeepsie, and many of the Yale Alumni.

The Legislative Committee, comprising Messrs. James W. Husted, L. Bradford Prince, James C. Osgood, Samuel J. Tilden, Severn D. Moulton and John Siimpson.

Among the many distinguished persons present were Gen. Sickles, and ex-Congressman Robinson of Brooklyn, who rendered efficient service to Prof. Morse in his first efforts to secure assistance from Congress for the telegraph, and stood by his side when the first message was sent.

THE BODY

was contained in a casket covered with black cloth, with silver heading and rich silver mountings.

The ball-bearers, who wore white scarfs, with black knots at the shoulders, took their seats in front of the pulpit. The casket was then partly opened, exposing the features of the deceased. Flowers were strewn over it, and in the centre was the following inscription:

SAMUEL F. B. MORSE,
Born April 27, 1791.
Died April 2, 1872.

After the audience was seated the choir sung the anthem,

"I HEARD A VOICE FROM HEAVEN,"

From the Greatorex collection. Dr. Adams read appropriate selections from the Scriptures, and the hymn, "Asleep in Jesus, blessed sleep," was sung by the choir to the tune of "Rest," both words

Digitized by Google

and music being favorites of the deceased. The following address was then delivered by Dr. Adams:

ADDRESS.

How poor and paltry the words of man in the presence of the great mystery of death! How weighty, how sublime those words of God with which we are bidden on such occasions to comfort one another: "Being born again, not of corruptible seed, but of incorruptible, by the word of God, which liveth and abideth forever. For all flesh is as grass, and all the glory of man as the flower of grass. The grass withereth and the flower thereof falleth away. But the word of the Lord endureth for ever, and this is the word which by the Gospel is preached unto you." Two aspects here of man. According to the one he is frail and fading as the flowers which love strews over his bier. According to the other he is imperishable and abiding as the Word of God.

The true value of a good life can never be lost to the world. The good which men do lives after them, and cannot be interred with their bodies. Abel, the first one of our race who tasted death, being dead, still speaketh. He is the true Methuselah who originates good thoughts and projects, which live a thousand years after he has passed from the world.

Two days ago a funeral procession filed through our streets with muffled drum, flags draped with black, and every sign of public woe, bearing the remains of one whom we all loved and honored to their last resting-place. As the pageant went by you said to yourself, such is the end—life all over, and like a vaper vanished away. Not so. The fidelity and loyalty of the brave Christian soldier are not lost and cannot pass away, but have entered as permanent properties into the life and history of his country.

Preeminently true is this of the distinguished man, whose death has brought us together at this hour. If it be true, according to the Scripture, that no man dieth to himself, emphatically true is it, that the death of such a man is like the fall of an oak in a grove, creating a wide chasm, and bearing many vines and trees and boughs with it to the ground. Deep as are the sorrows in the home circle, and in private intimacies, occasioned by this event, his death cannot be regarded but as a public bereavement. We sorrow not alone; millions have shared the shock. One is awed by the thought that no sooner had death come to this dear and honored friend, than by means of the instrument which his genius had perfected, the intelligence was sobbed beneath the billows of the western ocean, across the continents eastward and westward, and simultaneously was the topic of remark and the occasion of grief in London, Paris, Rome, Vienna, Berlin, St. Petersburg, Syria, Egypt, India, China, Australia, Japan, and in every part of the civilized world. We say, in familiar phrase, he is dead; but in the best sense he lives still, and will live for ever, in forms of usefulness which are intimately related to the concord, the welfare, and the advancement of the whole human race.

Samuel Finley Breese Morse was the oldest son of the late Rev. Dr. Jedidiah Morse, of Charlestown, Mass., and was born at that place April 27, 1791, and consequently was, abating a few days, eighty-one years of age at the time of his decease.

His youngest brother, Mr. Richard C. Morse, was buried from this church less than four years ago, being seventy-four years old. The brother next in years, Mr. Sydney E. Morse, departed this life in December last, occasioning a shock to their surviving brother, which never passed away but in his own death. So it has occurred in the providence of God, that I have been called to officiate at the interment of all three of these fond and confiding brothers, and have related many incidents of the remarkable family from which they sprung. It is not necessary to repeat these incidents again, though every repetition confirms me in the deliberate opinion, justified by well-known facts, that no one family in these United States has, by direct and indirect influence of father and son, been related to more acts and agencies of great importance and usefulness to the church and the country, than that of Dr. Jedidiah Morse.

While the name of that father has attained great notoriety by reason of his public works, let not the name and influence of his mother be unhonored. Her features are retained on canvas by the hand of her own son. No one can look on the picture of his mother reading by candle-light, even though uninformed that she was the descendant of an illustrious ancestry, without perceiving that she was a woman fitted to train and inspire her sons for high ends in life. As I have seen him look oftentimes on that picture, which his own heart had created, I have invariably recalled the words of Cowper, when gazing upon the picture of his own mother:

"My boast is not that I deduce my birth
From loins enthroned and rulers of the earth,
But higher far my proud pretensions rise,
The son of parents passed into the skies."

Some lives there are which have all the interest and charm of an epic poem, so wonderful are the conjunctions of providential events which enter into their plan and evolution. The most rapid reference to some of the incidents in the life of Prof. Morse, is all that can be expected on this occasion.

Graduating at Yale College in the year 1810, and developing an early fondness for art, he went abroad for the purpose of study. A pupil of Benjamin West, the intimate associate of Allston, Leslie, and Coleridge, of whom he abounded in felicitous reminiscences, he returned to this country, bringing with him the honorable testimonials of his success. Fond of his profession, the founder and President of the Academy of Design in this city, and expecting to devote his life to the art of painting, it was owing to a singular incident associated with the fidelity of his father in the advocacy of evangelical truth in Massachusetts, that he was diverted from the pencil and the brush to those studies and experiments which resulted in the inventions which have given him his world wide renown.

I have no intention, at this time and place, to give the detailed history of his connection with the magnetic telegraph. As those various associations of science and art with which he was connected, will vie with each other in vindicating the truth of this matter, I shall intrust that eulogy to them, passing myself to those moral and religious aspects of his life and work, which seem to me the most appropriate to be uttered by a Christian minister in the sanctuary where he was so long accustomed to worship.

This I am sure is the method which most accords with the modesty of our deceased friend; for, while the world was filled with the splendor of his success, such was the genuine quality of his religious faith, that first and last, he delighted to regard himself as the child and agent of Providence. That first message which was flashed through the first public telegraph wire, put into words by a privileged friend at his side, "What has God wrought!" was no affectation, but the sincere expression of one who always devoutly felt his dependence on Divine Providence throughout the whole success.

The period of time, in the history of the world, when telegraphic communication was established, is not the least of the many providential aspects which command our notice. The early and long segregation of nations, prior to the Christian era, was no accident. So long as Christianity was not ready for the world, the world was not ready for Christianity. The isolation of one nation from all others, to be the depositary of Divine revelation, seems to have been a necessary part of the Divine plan. As Christianity grew ripe and ready for replanting, propogation and reproduction, corresponding changes in the relations of different nations became apparent; as those changes went on in the revolutions and reformations of successive generations, it became evident, especially in that resuscitation of spiritual and reformed Christianity, which, during the early part of this century, passed like the breath of Spring over Protestant Christendom, signs were everywhere visible of an intention on the part of Providence to break down international barriers, and by a general inter-communication and fusion of all peoples, to introduce an era of universal interdependence, fraternity and unity.

In this, and not in an earlier period, when it would have been unavailing for good, was the magnetic telegraph brought into use. As the inventor of the instrument which bears his name, Professor Morse, honest and true, never detracted from the merits of discoverers and inventors who preceded him in time; but, from beginning to end, was the foremost to do them honor. Many have supposed that an inventor must be like an insulated jar, hermetically sealed, with no connection with other minds. Whereas, he is rightfully permitted to avail himself of all which he can gather from all sources, books and men; even as a wise master-builder coming upon the ground, where blocks of marble lie in confusion all around him, puts each and all in their proper places, and the whole building rises in order and symmetry to completion.

The highest forms of heroism are those with which good men devote themselves through faith, with patient unintermitted toil and self-sacrifice, to the accomplishment of those objects which look only to the welfare of the race. Milton in his day, mourned over the fact that the world was so intent on admiring its military destroyers, that it had no time to honor those, its benefactors, who were engaged unapplauded in laying the foundations of human improvement. Seldom does it occur that great inventors, sons of science, are permitted to see and enjoy the full results of their success. Generally it has been with them, as with the old Hebrew prophets, of whom we read, that "not unto themselves, but unto us did they minister;" "not having received the promises, but having seen them afar off and were persuaded of them." Like others of his class, Professor Morse, at the beginning of his experiments, was no stranger to trial and opposition. Those who saw him in that upper turreted room of the University, where, like the "Tuscan artist on the top of Fesole," he gave himself to midnight thought and study, will never forget the patience of his faith and hope amid manifest discouragements. To him was alloted, as if he were one of the few noble to whom it was safe that it should be so alloted, the rare privilege of seeing the complete success, and enjoying the full honor and reward of his great invention. He struggled with difficulties and delays, with privations, with ridicule in high places, but he lived to be crowned with more honors and insignia from the different governments and crowned heads of the world, than ever were alloted to any private citizen of our republic. Well has it been said, distinguished merit sooner or later, rises superior to opposition, and draws lustre from reproach; as the clouds, which in the morning veil the sun and darken its early career, arrange themselves at the hour of its setting, into a brilliant and magnificent array, taking and reflecting glory from its descending rays.

Very seldom, in the history of men, is there to be seen a life so complete as his in all its parts. "Them that honor me I will honor," says the God of the Scriptures. "Length of days, peace, riches and honor," are the promised gifts of divine Wisdom. Promises how well fulfilled in the case of this honored friend. He saw all the nations of the world knitted together by nerves and cords of immediate intercommunion. Remembering as I do his earliest experiments, and the modest confidence of his words at the first public exhibition of his invention, "I see not any limit to its power, and why it may not act around the world," what a pleasure it was to me to report to him on my return from successive visits abroad, the daily use I had made of his telegraph, among the mountains and valleys of Switzerland, and invariably did his response include a most grateful and admiring reference to the agency of Divine Providence.

A few days before his decease, in the privacy of his chamber, I spoke to him of the great goodness of God to him in his remarkable life. "Yes, so good!" was his quick response, "and the best part of all is yet to come." Spared to see more than eighty years, he saw none of the infirmities of age either in mind or body. His delicate taste, his love for the beautiful, his fondness for the fine arts, his sound judgment, his intellectual activity, his public spirit, his intense interest in all which concerned the welfare and decoration of the city, his earnest advocacy of Christian liberty throughout the world—continued unimpaired to the last. With perfect health, in full possession of every faculty, urbane and courteous, there was no infelicity of temper or manner, such as sometimes befalls extreme age. Surrounded by a young family, he was their genial companion and friend, sympathising in all those pleasures and innocent things which give a charm to home.

The greatness which consorted with sages was associated with that simplicity, which, as by affinity of tastes, attracted little children to his arms. In particular qualities he had many equals and superiors, but in that rare combination of excellences which, like the harmony of colors in a finished picture, made him what he was, he

Digitized by Google

was unrivalled. So that for these many years he has seemed to me, and this is the image of him in his life and death which I shall always retain, a personification of manly beauty, haloed with the glory which God gives to the hoary head, found in the way of righteousnes.

So I come to speak more distinctly of our friend as a disciple of Jesus Christ. In speaking of him as a Christian I would wish to avoid all vague and indefinite language. Much more would I deprecate mere technical words. Peculiar opportunities have I enjoyed for forming a judgment of his Christian character. Religion with him was something more than a thin varnish over his own pictures, designed to bring out their light and shade. It was wrought into the very substance of his soul and life. His convictions of truth were very discriminating. He was not only fond of, but a proficient in theological literature. As a worshiper and devout listener in the house of God, he evinced that magnetic sympathy with the preacher which every pastor feels, though he cannot describe. Especially did he kindle into enthusiasm at all words which aimed to honor and glorify his divine Lord. Distinct impressions have I of particular occasions when he gave utterance, with special emphasis, to his religious emotions. Last autumn he was occupied officially, with many of our fellow-citizens, in acts of attention to the representative of the royal house of Russia. At the holy communion in this church next ensuing, an occasion in which, for domestic reasons, he felt an extraordinary interest—at the close of the service he approached me with a more than usual warmth and pressure of the hand, and, with a beaming countenance, said: "This is something better and greater than standing before princes."

His piety had the simplicity of childhood. Will his household ever forget the heartiness and reverence of their family worship? The word of God, was it not his daily meat and drink? Will those who have so many years seen him in this house of God, ever part with the image of his earnest devotion?

While others speak of the brilliancy of his public honors, the success of his life in the judgment of the world bordering even on the creations of romance, these are the things which are to be magnified above all else. He was a sincere believer, a true, modest, humble, happy disciple of Jesus Christ. So was he for many years, even from his youth. His departure corresponded to his life. No perturbations of body or mind; all was calm, dignified, and beautiful. Industrious in his library, writing every day, in that clear, perfect penmanship for which he was remarkable, up to those last few days of seclusion in his chamber, where life was to end, everything was in keeping with his habitual serenity and sweetness. When sleeping away into apparent unconsciousness, he would always respond with animation to the mention of the name and promises of our Saviour. When it was surmised by some that he had passed beyond all power of intelligent communication, I repeated those great words of apostolical confidence, "I know whom I have believed;" he instantly replied, "I know him, too—certainly I do—it is all right." Believing, as I do, that the sick and dying are oftentimes disturbed by officious words and inquisitiveness, and content if able to hold up to the rayless eye some simple object from the Scriptures, I began the recitation of some short sentence, when he would take it from my lips, and complete the quotation.

Last Sabbath noon he had lost the power of articulation, and, as friends supposed, his consciousness also. Waiting at his side for the intelligent opening of his eye, I repeated to him the text from which I had just preached an Easter sermon, "Thanks be to God who giveth us the victory, through our Lord Jesus Christ." Instantly he nodded assent, and, with a speaking pressure of my hand, gave me to understand that through faith in his Redeemer he was a conqueror, and more than a conqueror. What are all victories ever won upon the earth compared with that calm and fearless conquest over death and the grave which is given to those who believe in Jesus?

The agencies by which the coming of the kingdom of God among men is to be accelerated are many and various. The telegraph was from its inception consecrated by prayer. I speak that which I do know, when testifying that when the project was formed and accomplished of laying the electric wires beneath the sea, more than one of its projectors not only implored devoutly divine aid, but in God's name dedicated it to the great cause of human brotherhood and kindness. I am told by one who can speak advisedly on this subject, that among all the messages which have been sent from nation to nation concerning all things great and small, diplomacy, commerce, marriages, births, deaths, it is not known that one unkind, one angry, one profane word has ever passed. One of the last, if not the very last public communication from Professor Morse, was a letter written to the International Telegraphic Convention recently held in the city of Rome, in which in view of the possible contingency of wars, occurs the following sentence: "In the interest of human happiness, of that peace on earth which announcing the advent of the Saviour, the angels proclaimed with good will to men, I hope the Convention will not adjourn without adopting a resolution asking of the nations their united effective protection to this great agent of civilization."

Over the bier of the good man by whose hand that sentence was penned let us all pledge ourselves to devote life and faculty to the promotion of that kingdom which is righteousness, and peace, and joy in the Holy Ghost.

How direct the agency of that instrument which is now in our thoughts, may be on the kingdom of Christ upon the earth, we may not say. It is possible that in those great events which are to be unfolded in the future, a more literal sense may be given to those words of our Lord, than has entered into our minds: "As the lightning cometh out of the East and shineth even unto the West, so shall also the coming of the Son of man be." So it may occur in those halcyon days which inspired prophecy has taught us to anticipate, when wars and rumors of wars shall cease, and violence shall no more be heard, and the promised king of all the earth shall come down like rain upon the mown grass, and as showers that water the earth, in whose days the righteous shall flourish and abundance of peace so long as the moon endureth—that from the uttermost parts of the sea the word shall be given forth, "the Lord is here:" and from worshiping millions at the opposite pole, bathed and blessed in the love of Christ, the response shall come back, "the Lord is here:" for the earth shall be full of the knowledge of the Lord as the waters cover the sea. He makes the most of life who of set purpose devotes himself and all which God has given him to the promotion of that great end.

To-day we part for ever with all that is mortal of that man who has done so much in the cause of Christian civilzation. Less than one year ago his fellow-citizens, chiefly telegraphic operators, who loved him as children love a father, raised his statue of bronze in our Central Park. To-day all we can give him is a grave.

Farewell, beloved friend, honored citizen, public benefactor, good and faithful servant. While thy eulogy shall be pronounced in many languages by thy fellow men, this I believe, was your own highest aspiration—to have your name as a humble disciple written in the Lamb's Book of Life. There it will shine, and ours also, even the humblest of us all, if united to Christ, above the brightness of the firmament and as the stars for ever and ever. A small thing is it to be judged of man's judgment; and all the greatness and glory of this world passes away like a dream. "God excepteth not the persons of princes, nor regardeth the rich more than the poor; for they all are the work of his hands." Truly great and immortal is that man, however obscure his earthly lot, who so believes in Jesus Christ that he may appopriate to himself the words of the Lord of Life, "because I live ye shall live also."

The three grandest objects which ever can occupy the mind of man are the Redeemer, the human soul, the day of death and judgment. Blessed is that man and so will he be when all the thrones, monuments and eulogies of the world are forgotten—who so lives that he shall be able to combine the three and say, as did this true christian in his last articulation, "I know whom I have believed—and am persuaded that he is able to keep that which I have committed to him against that day."

Prayer followed by the Rev. Dr. Wheeler, and the chant "Just as I am without one plea," was rendered by the choir. An opportunity was then given to take a last look at the venerable face of the distinguished professor, and while the organist played a funeral march of Chopin, the immense audience slowly moved up the centre aisle past the coffin, and dispersed. The congregation manifested the greatest respect and reverence for Prof. Morse, but there were few indications of mourning, the prevailing feeling seeming to be that a noble life, crowned with the greatest of earthly successes and honors, had reached a fitting and worthy end.

At the conclusion of the services at the Church, the remains were taken to Greenwood Cemetry and deposited in the receiving vault. The burial service was read and prayer offered by the Rev. J. A. Hodge of Hartford, son-in-law of the late Richard Morse, and the benediction was pronounced by the Rev. Dr. Wheeler.

The following letter, which is entirely in Prof. Morse's handwriting, will show that old age did not impair the vigor of his faculties. The chirography is wonderful for its clearness, and would do credit to any young man. Below is the letter, which speaks for itself:

We may add that when this letter was read at the convention in Rome, prolonged cheers were given for its author, and the letter itself was ordered to be printed among the records of the convention.

NEW YORK, Dec. 4, 1871.

MY DEAR MR. FIELD: Excuse my delay in writing you. The excitement occasioned by the visit of the Grand Duke Alexis has just closed, and I have been wholly engaged by the various duties connected with his presence.

I have wished for a few calm moments to put on paper some thoughts respecting the doings of the Great Telegraphic Convention, to which you are a delegate.

The telegraph has now assumed such a marvelous position in human affairs throughout the world; its influences are so great and important in all the varied concerns of nations, that its efficient protection from injury has become a necessity. It is a powerful advocate for universal peace. Not that of itself it can command a "Peace, be still!" to the angry waves of human passions, but that by its rapid interchange of thought and opinion it gives the opportunity of explanations to acts and laws which in their ordinary wording often create doubt and suspicion.

Were there no means of quick explanation it is readily seen that doubt and suspicion working on the susceptibilities of the public mind would engender misconception, hatred and strife. How important then that in the intercourse of nations there should be the ready means at hand for prompt correction and explanation.

Could there not be passed in the great International Convention, some resolution to the effect that in whatever condition, whether of peace or war between nations, the telegraph should be deemed a sacred thing, to be by common consent effectually protected both on land and beneath the waters?

In the interest of human happiness, of that "Peace on earth" which, in announcing the advent of the Saviour, the angels proclaimed with "good will to men," I hope that the Convention will not adjourn without adopting a resolution asking of the nations their united effective protection to this great agent of civilization.

The mode and the terms of such resolution may be safely left to the intelligent members of the honorable and distinguished Convention. Believe me as ever, your friend and servant,

SAMUEL F. B. MORSE.

Hon. Cyrus W. Field, Rome, Italy.

Thus with vigor of mind unimpaired, with steady hand and undimmed eye, with peace in his heart and "Peace on Earth" on his lips, Professor Morse ended his earthly mission.

OFFICIAL.

NEW YORK, April 4, 1872.

To all telegraph Superintendents and Managers in the United States and Canada. All that is mortal of the venerable, and venerated father of the American telegraphic system, Prof. Samuel F. B. Morse, will be consigned to the grave on Friday, April 5th. No expression or outward exhibition can give fitting evidence of the sorrow which his death has occasioned among those connected with the telegraph, or within the reach of its influence, not only in America, but throughout the world, but in token of respect to his memory, some symbol of mourning should be exhibited at all telegraph stations on the day of burial, a simple rosette, or a bit of crape will suffice.

WILLIAM ORTON, Pres't.

TRIBUTES TO HIS MEMORY.

THE DEAD JUPITER.

[Professor S. F. B. Morse. Obiit April 2, 1872.]

BY A. B. WATSON.

To-day a God died.—*Thomas Baily Aldrich.*

Draw near and see our Jupiter, who, dead,
Upon this stretcher is a-lying here!—
"What! a god dead!—I'd see dead Jupiter!"
Come see! Aye, this must be a god's—this head;
The cheek has lost its last faint blush of red;
There are no bolts in those dead hands to fear!
The weasels are purposeless. You can stand anear!
He's wrathless now for lo, our Jove is dead!
"But was he Jove? On what point have ye hung
So fair opinion of him?" Did not these hands
Weave the enchanted lightning into brands,
Tongue-burthened and obedient, that have strung
A zone of speech around the world, to prove
The fame of him who's dead there? He is Jove.

ACTION OF CONGRESS.

In the House of Representatives Mr. Cox, of New York city, offered a concurrent resolution, which was agreed to, declaring that Congress has heard with profound regret of the death of Professor Morse, whose distinguished and varied abilities have contributed more than those of any other person to the development and progress of the practical arts, and that his purity of private life, his loftiness of scientific aims and his resolute faith in truth render it highly proper that the Representatives and Senators should solemnly testify to his worth and greatness.

Mr. Wood, of New York city, gave a brief history of the legislation under which Professor Morse's invention was practically tested in the United States. He (Mr. Wood) was a member of the Twenty-seventh Congress, to which Professor Morse made application for aid to test his invention. It was in the winter of 1842 and 1843 when Mr. Morse came to Washington in a state of pecuniary dependence, broken down by disappointment and almost entirely discouraged. With great difficulty the proposition appropriating $30,000 was got through the House by a vote of 89 to 87. It was with great pride that he (Mr. Wood) found his name recorded in the affirmative, and he was to-day the only living member of either house who voted in favor of the bill. With that small appropriation the first wires were stretched between Baltimore and Washington, which tested and proved the entire practicability of the invention which Professor Morse had struggled so long to make a practical success.

THE NEW YORK LEGISLATURE.

ALBANY, April 3, 1872.

Resolutions relative to the testimonial of Professor Morse, and ordering that a committee be appointed to attend his funeral were adopted. It was also suggested that his statue be placed in the Capitol at Washington in place of, or in addition to, the statue of Robert Fulton.

GOVERNOR HOFFMAN'S COMMUNICATION.

ALBANY, April 3. 1872.

The Governor sent in by his private secretary the following communication:

STATE OF NEW YORK, EXECUTIVE CHAMBER,
Albany, April 3, 1872.

To the Legislature:

The telegraph to-day announces the death of its inventor, Samuel F. B. Morse. Born in Massachusetts, his home has for many years of his eventful life been New York. His fame belongs to neither, but to the country and to the world; yet it seems fitting that this great State, in which he lived and died, should be the first to pay appropriate honors to his memory. Living, he received from governments everywhere more public honors than were ever paid to any American private citizen; dead, let all the people pay homage to his name.

I respectfully recommend to the Legislature the adoption of such resolutions as may be suitable and the appointment of a joint committee to attend the funeral of the illustrious deceased.

JOHN T. HOFFMAN.

HONORS TO MR. MORSE.

Resolutions of the State Senate in honor of the late Inventor.

Special dispatch to the New-York Times.

ALBANY, April 6.—The Senate Committee to draw up resolutions relative to the death of Prof. S. F. B. Morse, on Saturday reported the following:

The undersigned Committee, appointed to draft appropriate resolutions for the memory of Prof. S. F. B. Morse, beg leave to report the following:

Resolved, That the Senate have heard with profound regret of the death of Samuel F. B. Morse, whose achievement of science in rendering the electric telegraph of practical usefulness, has constituted him one of the greatest benefactors of the human race, and that they recognize this official expression as eminently due to his memory.

Resolved, That we remember with pride, that, while a citizen of this State, his thought conceived and skill formed the art which has marked a new era in the progress of civilization.

Resolved, That the career of Prof. Morse through all the discouragements which beset him, is the pride of this his adopted State, and that these resolutions be entered upon the Journal of the Senate, and that a copy thereof, duly certified, be transmitted to the family of the deceased.

Committee.—WM. B. WOODIN,
H. C. MURPHY,
D. P. WOOD.

The resolutions were unanimously adopted.

MEETING IN WASHINGTON—ARRANGEMENTS FOR A NATIONAL MEMORIAL CELEBRATION AT THE CAPITOL.

WASHINGTON, April 4, 1872.

A large meeting of citizens of Washington was held here this evening to take action in relation to the death of the late Professor Samuel F. B. Morse, Professor Hedrick acting as Chairman and H. Amidon as Secretary. Arrangements were made to obtain the use of the hall of the House of Representatives for imposing memorial services in honor of the late Professor, to take place, probably, on Monday evening, April 15, at which distinguished gentlemen will deliver addresses. The Secretary of the Navy has offered the Marine Band for the occasion, and the Washington Choral Society, which won a prize at the recent musical festival in New York, have volunteered their services.

Mr. A. S. Solomans offered the following resolution, which was unanimously adopted:

Resolved, That the people of the United States be requested to meet in their respective cities, towns, and villages on the evening of the —— day of April, at eight o'clock, to give expression to the loss sustained by the world in the death of Professor Samuel Finley Breese Morse, and to hold simultaneous communication by telegraph with the assembly of the people's representatives and the citizens of Washington, convened for the like purpose in the capital of the nation.

To this the Western Union Telegraph Company sent a prompt response:

A. S. SOLOMANS, ESQ.:

MY DEAR SIR:—I am authorized by Mr. Orton, our President, to say to you that the Company will cheerfully grant the use of our wires, for direct communication between the simultaneous Morse memorial meetings, which it is proposed to hold. Please advise me of the date fixed upon for the meeting.

Very truly, yours,
LEONARD WHITNEY, Manager.

A committee of five on resolutions, with Senator Patterson as chairman, and a committee of arrangements of fifteen, with Mr. A. S. Solomans as chairman, were appointed, with full power to act, and the meeting adjourned.

The following resolution was passed by the National Telegraph Morse Memorial Association.

WHEREAS, The United States House of Representatives has placed the Hall at the disposal of this Association for the purpose of holding a memorial meeting in honor of the late Samuel F. B. Morse, on Tuesday, April 16, and prominent members of both houses of Congress have consented to address the meeting; and,

WHEREAS, Telegraph wires have been freely placed at the disposal of this association for that evening; therefore,

Resolved, That the municipal authorities of the cities and towns of the United States are hereby invited to hold meetings of a similar character in their several localities on the same evening, in order that the meetings may be in telegraphic communication, and thus a simultaneous expression be given to the national grief on the occasion of this irreparable loss.

MASSACHUSETTS.

Resolved, That the Legislature of Massachusetts has learned, with profound regret, of the decease of Samuel Finley Breese Morse, the distinguished inventor of that wonderful system of electric telegraphy which is conferring unspeakable blessings upon the whole human family.

Resolved, That, born upon our soil, and under the very shadow of this capitol, his name will ever be associated by the people of this state with that of another of her illustrious sons, who demonstrated to the world the existence of that mighty but subtle agency, which the genius and skill of his peer and successor has brought under subjection and made subservient to the will of man.

Resolved, That with the regrets his death has occasioned are mingled emotions of joy and gratitude that he was permitted by Him in whose hands are the issues of life and death, to attain to the full age allotted to man upon the earth, and that he was thereby enabled to witness the complete triumph of the work to which his life was consecrated—a privilege which has seldom been enjoyed by the world's greatest benefactors.

Resolved, That his excellency the governor be requested to transmit a copy of these resolutions to the family of the deceased, with the assurance of the sympathy of the people of this commonwealth in the loss they have sustained.

THE WESTERN UNION TELEGRAPH COMPANY.

NEW YORK, April 3, 1872.

A meeting of the Board of Directors of the Western Union Telegraph Company, was held at the office of the Company, 145 Broadway, to-day, to take action relative to the death of Professor Morse. A committee consisting of Ezra Cornell, Hiram Sibley, Sir Hugh Allan, Cambridge Livingston, Dr. Norvin Green, Edward S. Sanford and Willam Orton were appointed to prepare suitable resolutions expressive of the feelings of the Company at the decease of Professor Morse. The following resolutions were adopted:

WHEREAS, the Board of Directors of the Western Union Telegraph Company, have learned of the death of Professor Samuel F. B. Morse, the father of the American telegraph system, whose name has become justly identified with the establishment of the telegraph throughout the world, therefore,

Resolved, That we mourn with the entire civilized world, the loss of one of the great benefactors of the age, and we grieve for a friend and associate whose purity and simplicity of character and kind and gentle nature have endeared him to our memories. While his great achievement will continue to bless and benefit the enlightened races of mankind, the memory of his personal worth will ever remain in the hearts of all who have had the good fortune to know him.

Resolved, That we unite in the universal expression of sorrow which is this day being transmitted to and echoed back from all quarters of the earth by means of his transcendant achievement; and we hereby tender our earnest sympathy to the family of our friend.

Resolved, That this Board will attend Professor Morse's funeral in a body.

THE NEW YORK, NEWFOUNDLAND AND LONDON TELEGRAPH COMPANY.

At a meeting of the Directors of the New York, Newfoundland and London Telegraph Company, held at the City Bank, on the 3d day of April, 1872, it was unanimously

Resolved, That the Directors of this Company have heard with deep regret of the decease of Professor Samuel F. B. Morse, who died last evening at his residence in this city,

Resolved, That we grieve for the death of Professor Morse, not only because he was a distinguished philosopher and the founder of the telegraph system, which has so changed the relations, commercial and social, of the world, but because he was our intimate associate and friend, having been connected with this Company for the last eighteen years, and that we tender to the family of the deceased our sympathies in the hour of their affliction.

Resolved, That the Directors of the company will, in a body, attend his funeral, and that a copy of these resolutions be transmitted to his family and entered on the minutes of this Board.

EDWIN F. HATFIELD, Jr., Secretary.

THE BROOKLYN POLICE.

Chief of Police P. Campbell caused the following order to be sent to the captains of precincts of Brooklyn yesterday morning:

You will cause the flag on your station to be displayed at half-mast until further orders, out of respect to the memory of Professor Morse, the Father of Telegraphy.

CHAMBER OF COMMERCE.

Mr. George W. Dow, at the Chamber of Commerce, offered the following resolutions, which were unanimously passed.

Resolved, That the members of this Chamber have learned with sorrow and regret of the death of Professor Samuel F. B. Morse, a gentleman whose name has become cosmopolitan, and whose great scientific invention—"wrought by God," as he gratefully acknowledged—has electrified the whole world by giving to our globe a nervous system of far-reaching and quick intelligence which has astonished mankind by its marvelous activity and power in the dissemination of ideas and the advancement of commerce and civilization. As an American citizen and inventor of eminence, we will cherish and respect his memory. His fame belongs to all nations, and will shine forth illustriously in the galaxy of man's great benefactors. As representatives of mercantile interest, which have so largely reaped the benefits of his skill and perseverence we acknowledge our indebtedness to him, and we hereby respectfully tender to his widow and family our sincere sympathies at this time of their bereavement.

Resolved, That the foregoing be entered on the minutes of this day's proceeding, and that a copy of the same be suitably engrossed and forwarded to Mrs. Morse.

It was afterward resolved by the Chamber to attend the funeral in a body, and all members are requested to assemble at the church at 10 o'clock this morning.

BROOKLYN COMMON COUNCIL.

A special meeting of the Brooklyn Common Council was held last evening to give expression to their feelings on the death of Prof. Samuel F. B. Morse. The following preamble and resolutions were adopted:

WHEREAS, It has pleased an all-wise Providence to take from among us, in the calm serenity of a ripe old age, one of the world's benefactors, Samuel Finley Breese Morse, the inventor of the American telegraph system; and

WHEREAS, The electric telegraph, in its almost miraculous results, annihilating, as it does, time and distance, spanning oceans, climbing mountains, and, with the exception of one short gap, girding to-day the entire globe, ranks with those miraculous inventions, the printing press and steam engine, the benefits of which are shared by the whole human race; therefore

Resolved, That we, the Common Council of the City of Brooklyn, mourn, with the rest of the civilized world, the loss of Prof. Morse, whose kind and gentle nature and pure and christian life, no less than his great genius, must ever endear him to our memories.

Resolved, That we tender to the family of Prof. Morse our earnest sympathy in the loss they have sustained, and that this Board will attend his funeral in a body.

Resolved, That as a further expression of our respect and sorrow, flags be displayed at half mast on the City Hall to-morrow, April 5th, the day of his funeral.

Resolved, That a copy of these resolutions suitably engrossed and framed, be prepared and transmitted to the family of the deceased.

TROY COMMON COUNCIL.

TROY, April 4,—At a meeting of the Common Council, this evening, the following message from the Mayor was read, and the resolution adopted:

To the Honorable the Common Council:

Samuel F. B. Morse was one of the master men of the world, and a benefactor of the race. His death, like that of a Franklin or a Washington, calls for a universal expression of regret. Respectfully,

THOMAS B. CARROLL, Mayor.

Alderman Wilkinson, in response to the Mayor's cummunication, offered the following resolution.

The City of Troy in Common Council convened, have heard with deep sorrow of the death of Samuel F. B. Morse, the great electrician, and would put on record this utterance as a testimonial of regard for his services and respect to his memory.

The resolution was unanimously adopted.

NEW YORK STOCK EXCHANGE.

A meeting was held at the Stock Exchange, yesterday, and a series of resolutions was passed, expressive of the public loss sustained in the death of Professor Morse. Mr. S. V. White, a member of the Board, delivered an address eulogistic of the deceased. A copy of the resolutions will be presented to the family. As a mark of respect, the two regular calls of Stock will be omitted at the Exchange.

The following resolutions were passed at a meeting of the Board of Directors of the Empire Mutual Life Insurance Company:

Resolved That we have learned with great sorrow of of the death of our associate, Prof. Samuel F. B. Morse; that while we mourn with the whole world the departure of one whose name is indissolubly connected with one of the greatest improvements of the age, we grieve still more at the loss of an intimate friend, whose culture, gentleness and broad sympathies won the profoundest regard of all who were favored with his companionship.

Resolved. That we tender to the family of the deceased, our deepest sympathy in their great affliction, and that the President and Secretary be requested to furnish them with a copy of these resolutions.

NATIONAL ACADEMY OF DESIGN.

Appended are the resolutions passed by the National Academy of Design.

Resolved. That, in common with the rest of the world, it becomes our painful duty to recognize the passing away from among us of Prof. Samuel F. B. Morse, our first President—we may almost say the very founder of our institution—a man endeared to many of us by still closer personal ties, the last of a trio of painters from whom have preceded during the past century the three perhaps most remarkable inventions of the age, in their widespread and still spreading influence upon mankind, for Fulton, Daguerre and Morse are names which will hereafter associate themselves in the minds of men to a very remote stretch of time. He would be bold indeed who should venture to predict the enormous result that may yet grow out of these seeds even beyond their present development, or attempt to unvail all the possibilities of growth that yet he hid in the womb of time. We cannot but feel some pride in the share which study of our common profession must have had in developing those faculties with which he wrought the great telegraphic plan that makes his name forever famous. And though he has secured such a lasting name by other than the pursuit of that art with which he set out in life, had he confined himself thereto, there is little doubt among the best judges in art matters but that he would even there have left his among the roll of names that were not born to die. We desire to mingle our sorrows with those who were nearest and dearest to him in sympathy and condolence with their grief, and may he rest in peace.

Resolved, That we will attend the funeral of our deceased brother academician, and that these minutes be entered on the minutes, and a copy of them be transmitted to the family.

THE NASHVILLE OPERATORS.

At a meeting of the operators and other telegraphic employes of Nashville, held at the office of the Western Union Telegraph Company, at 3 P. M., April 4, for the purpose of taking appropriate action on the sad occasion of the death of Professor Morse, the meeting was organized by the election of Mr. Jo. W. Fisher, as Chairman, and Mr. E. C. Boyle, Secretary.

Messrs. Geo. W. Trabue, W. P. Gentry, and J. B. Morris, were appointed a committee to draft appropriate resolutions expressive of the meeting, and the following was reported by Mr. Trabue, Chairman of the Committee, and unanimously adopted:

WHEREAS, The melancholy tidings of the death of Professor S. F. B. Morse, at 7:43 P. M., April 2, has reached us, therefore,

Resolved, 1. That having long entertained for Professor Morse a filial regard inspired by habitual feelings of reverence towards him, as the illustrious Father of the Telegraph, and respect for his character and genius, we receive the intelligence of his death with the deepest sorrow and regret for this our own, and our countries loss.

Resolved, 2. That in the death of Professor Morse, the people of the whole world have lost one whose name does and will continue as long as time lasts, to illuminate and mark the century in which he lived as the brightest and best of all preceding centuries, and an age in which more has been accomplished for science, than any other, and one in which more great discoveries have been made, in the way of developing the materials and elements which God intended for the use and benefit of man, but which remained undiscovered and useless so many ages, for the want of determined and resolute men like Professor Morse.

Resolved, 3. That while it is the common duty of all his countrymen to honor his memory, it shall ever be our pride to cherish a more tender regard, and to emulate his many virtues as well as his immortal achievements in the art of telegraphy.

GEO. W. TRABUE, Chairman,
W. P. GENTRY,
JNO. B. MORRIS.

Pending the adoption of the resolutions, Messrs. Trabue and Gentry made very appropriate and interesting remarks, eulogizing the illustrious deceased, and urging the younger members of the profession to profit by his example of patience and perseverance, under the adversities attending the initiation of his wonderful invention, which, finally led to complete success, and crowned him with honors, seldom conferred upon man.

LOUISVILLE, KY.

LOUISVILLE, April 3d, 1872.

At a meeting of the Telegraph Operators of this city, the following resolutions were adopted:

WHEREAS, It has pleased the Divine Providence to call from our midst our dearly beloved and respected friend and benefactor, Professor S. F. B. Morse, the Father of Telegraph.

Resolved, That in this bereavement, the world has lost a scientific benefactor, a kind and noble man, an ornament not only to science, but to public and private life in all its phases, a loss which cannot be replaced.

Resolved, That we, the Telegraph Operators of this city drape our instruments in mourning, for a period of thirty days, and wear the usual badge of mourning for one week as a token of esteem for the departed.

Resolved, That we hereby tender our sympathies to the bereaved family in their deep affliction, and earnestly pray that God will alleviate their grief, and afford that consolation to their stricken hearts which God alone can give. Signed,

N. DEBREE, W. U. Telegraph,
CHAS. SMITH, "
L. SHELDON, S. P. & A. Telegraph,
AUGUSTUS MEADE, "
Committee.

JEFFERSONVILLE, Ind., April 4th, 1872.

At a meeting of telegraph operators connected with the J., M. and I. R. R. Co., held this day, the following resolutions were adopted:

WHEREAS, It has pleased Divine Providence to remove from our midst our friend and benefactor, Prof. Samuel F. B. Morse, the inventor and father of the telegraph—

Resolved, That in the death of this venerable man, through whose instrumentality all nations of the globe have been brought into one neighborhood, and whose matchless inventions have furnished honorable employment for our numerous fraternity, we, as individuals, thereby lose a dear and cherished friend, the world a philosopher, and our fraternity a father.

Resolved, That, as a token of our respect and esteem for the honored dead, we drape our instruments and wear the usual badge of mourning for thirty days.

Resolved, That we hereby tender our sympathies to the family and relatives of the deceased, earnestly praying that they may secure that true consolation in their great affliction through Him that doeth all things well.

Resolved, That a copy of these resolutions be forwarded to the JOURNAL OF THE TELEGRAPH, and to the various newspapers printed on the line of this railroad, for publication

Committee, A. L. EGGLESTON,
W. S. CONE,
H. H. PINNEY,
T. J. BAINE,
F. B. GEOGHEGAN.

CINCINNATI.

CINCINNATI, April 5.

The alarm bells of the Fire Department of this city tolled this morning, as a tribute to the memory of Professor Morse, as the funeral cortage is moving in the city of New York.

HUDSON.

HUDSON, N. Y., April 5.

The telegraph offices in this city are deeply draped in mourning to-day, and the flag on the *Register* office is placed at half mast, out of respect to the memory of the late Professor Morse.

HARTFORD.

HARTFORD, Conn., April 5.

Governor Jewell has ordered that the flag on the State House be placed at half mast to-day, out of respect to the memory of Professor Morse. The *Times* office flag is also draped in crape on the same account.

ST. LOUIS.

The main office, on Third and Olive streets, of the Western Union telegraph line, was heavily draped in mourning yesterday, as a token of respect to the memory of Professor Samuel F. B. Morse. The wrappings of woe were festooned from the windows of every story and also stretched across the street. A portrait of Professor Morse was also displayed on the Third street front.

MEETING OF CINCINNATI TELEGRAPHERS.

The death of Prof. Morse has plainly left a more than passing sorrow in the breasts of a majority of our people. Among no order of men was it felt so keenly and commented upon to such an extent, however, as among the telegraphic fraternity. Before news had been disseminated in the suburbs the telegraph offices of the Western Union and Pacific & Atlantic companies, and the telegraph poles, with some of the depot offices, were being draped in mourning.

The Western Union also had a large portrait of Prof. Morse draped, and displayed a Morse telegraph register in front of the buildings.

In the evening a called meeting of the fraternity was held in the basement of the Western Union Telegraph office, on Third street, and was presided over by the following named officers: President, G. T. Williams; Vice-Presidents, L. C. Weir, R. Lewis, W. W. Smith, J. C. Van Dusen, Geo. M. Lane, J. W. Sherwood, J. N. Miller, C. S. Rogers, J. S. Lyle, A. Hayward, Jas. E. Reeves, Geo. Floyd, J. C. Clegg, and J. D. Ellison; Secretary, B. H. Johnson.

The first business transacted was the presentation of a report of a Committee on Resolutions, of which the following is a copy:

WHEREAS, It has been the will of God to remove from us our greatly beloved benefactor and friend, Prof. S. F. B. Morse, the great originator of the telegraph,

Resolved, That we have lost at once a brother and a father, one whom we can not replace; the scientific world a great teacher, society a bright and noble ornament of spotless character, and America the inventor of the age.

Resolved, That as a token of esteem for the great deceased, the telegraphers of this city drape their instruments and wear the usual badge of mourning for the space of thirty days.

Resolved, That we extend our tenderest sympathies to the bereaved family in their great loss, and beseech that they may receive consolation from the Giver of all good and perfect gifts.

Resolved, That a copy of these resolutions be forwarded to the *Telegrapher*, JOURNAL OF THE TELEGRAPH, and the daily papers of this city for publication.

The resolutions were adopted and a motion offered by Mr. F. A. Armstrong, ordering the sending of a message, expressive of the sense of the meeting, to the various offices throughout the country also prevailed.

Dr. Nicholson, a telegraph inventor, was then called upon to address the meeting. The importance of the Professor's invention could not be estimated at the present day, but would appear in all its prominence in the light of centuries to come.

Mr. F. A. Armstrong, Manager of the Western Union Company of this city, was the second speaker. He gave a most interesting description of the services attending the dedication of the Morse statue in Central Park, New York city, several months ago. In the evening, at the Academy of Music, the house could hardly hold the mass that took possession of it, and the best people of New York city, with depudations of the same class from other cities, were present. When the lady arose to send the dispatch of greeting, skipping along the lightning freighted wires to the gulf, to the Pacific coast, to the Canadas, and to all intermediate States, a stillness of curious expectancy settled down upon the house. Then, as the aged Professor took his seat at the table and with firm hand transmitted his signature, the quiet was so intense that the telegraphers scattered through the apartments were enabled to distinguish the letters. As the last one sounded, they gave the signal for an outburst of genuine hearty enthusiasm that shook the building and moved with untold pleasure and gratitude to the heart of the old man.

His statue would stand for ages a monument to himself, and a standing source of congratulation to "his children," as he called the telegraph brotherhood. Prof. Morse had won a permanent niche in the temple of this world's fame, and the speaker fully believed he would be received into the next in the character of one who had lived a useful and Christian life on earth.

Mr. W. W. Smith, of the I. & C. Railroad Co., and an ex-telegrapher of high standing, delivered the concluding address. He indorsed the remarks of the preceding speakers, and said that he had also been in attendance at the unveiling of the statue. He had met him on one occasion since then, and Mr. Morse seemed to feel more real delight in speaking of the unveiling ceremony than in recalling all the honors which had been bestowed upon him by crowned heads. The speaker referred to his first visit to the Professor, and the kindly manner in which he had received him, and closed his address with the remark that, in the face of all his history, no higher eulogy could be bestowed upon him than to simply say, "He is dead. Not a soul regrets that he has lived."

NEW ORLEANS.

The operators of the Pacific and Atlantic Telegraph Company, and those of the Fire and Police offices, met last evening in a body at the City Hall, with Mr. Chas. A. Adams in the Chair, and Mr. T. J. Rodgers, Secretary. After the meeting was called to order, the following resolutions were proposed and unanimously adopted:

Resolved, That we learn with the most profound feeling of regret of the decease of our beloved master in the art telegraphic, Prof. S. F. B. Morse, and that we unite most heartily in the universal expression of sorrow which swells up from all quarters of the civilized world, which, through his genius, has made us as one family.

Resolved, That while deploring the loss of a man so great and good, and while extending to his family our most sincere sympathies, we may congratulate them and ourselves upon the fact that he had lived to see the utmost realization of his hopes, and goes peacefully to his grave, ripe with years, rich with honors, mourned by continents and traduced by none.

Resolved, That his memory is too closely enshrined in our hearts to require any outward semblance of mourning.

Resolved, That our thanks are due to the Western Union Telegraph Directors; also, to Governor Hoffman, of New York, for the prompt and appropriate manner in which they acknowledged the world's loss.

Resolved, That a copy of these resolutions be forwarded to the family of the deceased.

NEW YORK ARTISTS' FUND SOCIETY.

The Artists' Fund Society of New York has adopted the following tribute to the memory of the late Prof. Morse:

The members of the Artists' Fund Society, called to say a last farewell to their reverend friend and benefactor, Prof. S. F. B. Morse, would express their deep sorrow, relieved by a kind of sacred joy, when they remember his pure and faithful character, his successful labors for the arts of our country, his great achievement as an inventor, his Christian example, his happy and completely finished life, and his peaceful, triumphant death. Early devoted to art, he brought to its pursuit a cultivated mind, conscientious study, and sound practice, leaving works of high excellence, and proving that he was only withdrawn from the greatest success as an artist by the absorbing claims of his famed invention.

We are indebted to him for the foundation of the Academy of Design, for his firm championship of its independence, and for an example of a solid, simple, and permanent method of execution in harmony with the works of the great masters of painting. We recall with affection his paternal kindness as a master in art, his never-failing interest in all that pertained to our profession, his wise counsel to our Society, and his generous gift to its fund. We offer our earnest sympathies to his bereaved family, and invoke for them the highest consolations. By order the Board of Control.

JOHN F. KENSETT, President.
ALEXANDER LAWRIE, Secretary.
April 9, 1872.

SINGAPORE, 15th April, 1872.

To Cyrus W. Field, Esq., New York:

The Chamber of Commerce of Singapore, learned with deep regret the great loss that the telegraphic and scientific world have sustained in the death of Professor Morse. READ.

BOMBAY, 15th April, 1872.

To Cyrus W. Field, Esq., New York:

The Bombay Chamber of Commerce heard with great regret of Professor Morse's death, and records its sense of the great loss caused to the scientific world thereby.

NEW YORK, APRIL 15, 1872.

UNTO THIS LAST.

In the ripeness and mellow sunshine of the end of an honored and protracted life, Professor Morse, the father of the American telegraph system, our own beloved friend and father, has gone to his rest. The telegraph, the child of his own brain, has long since whispered to every home in all the civilized world that the great inventor has passed away. Men as they pass each other on the street say, with the subdued voice of personal sorrow, "Morse is dead." Yet to us he lives. If he is dead it is only to those who did not know him. To those who knew and loved him he lives still in life's brightest and most coronal glory.

It is not the habit of ardent affection to be garrulous in the excitement of such an occasion as this. It would fain gaze on the dead face in silence. The pen, conscious of its weakness, hesitates in its work of endeavoring to reveal that which the heart can alone interpret, in a language sacred to itself, and by tears no eye may ever see. For such reason, we, who have so much enjoyed the sweetness of the presence of this venerable man, now so calm in his last sacred sleep; to whom he often came with his cheerful and gentle ways, as to a son, so confiding of his heart's tenderest thoughts, so free in the expression of his hopes of the life beyond, find difficulty in making the necessary record of his decease. We can only tell what the whole world has known for more than half a month past, that on the evening of Tuesday, April 2, Professor Morse, in the beautiful serenity of christian hope, folded his hands upon his breast, and bade the earth, and generation, and nation he had honored, farewell. We felt the parting very keenly. We shed warm tears over him as the crowd passed the bier over which affection had just uttered an eloquent and loving eulogy. We felt a heavy sigh go out as we left the vault at Greenwood, where the heavy doors swung back hiding forever the form we loved, and we sit down now to make this record with a kind of sadness, that, as we were the first to open a telegraph office in America for the public use of his great invention, so now, we are ending our own career in the record of his decease. His death is, therefore, in some respect, our own. He went out by the everlasting gate, followed by the loving eyes of all the world, into the brightness of a fresh glory, with all his ermine on. We go out by one of earth's many doors, to enter new toils, and amid which to fall some day, quiet and unknown, as when the willow drops her leaf in the cool breath of the autumn night.

Among the many public notices of Prof. Morse's death, two alone have struck us as peculiarly felicitous, one of them evidently the result of a deep knowledge of its subject. We therefore quote the following language from the New York *Evening Post*, which, from our pen, might seem the exaggeration of an ill-regulated affection.

"The name of Morse will always stand in the foremost rank of the great inventors, each of whom has changed the face of society and given a new direction to the growth of civilization by the application to the arts of one great thought; that it will always be read, side by side with those of Gutenburg and Schœffer, or Watt and Fulton. This eminence he fairly earned by one splendid invention. But none who knew the man will be satisfied to let this world-wide and forever-growing monument be the sole record of his greatness.

Had he never thought of the telegraph he would still receive, in death, the highest honors friendship and admiration can offer to distinguished and varied abilities, associated with a noble character. In early life he showed the genius of a truly great artist. In after years he exercised all the powers of a masterly scientific investigator. Throughout his career he was eminent for the loftiness of his aims, for his resolute faith in the strength of truth, for his capacity to endure and to wait, and for his fidelity alike to his convictions and to his friends. His intellectual eminence was limited to no one branch of human effort, but in the judgment of men who knew him best, he had endowments which might have made him, had he not been the chief of inventors, the most powerful of advocates, the boldest and most effective of artists, the most discerning of scientific physicians, or an administrative officer worthy of the highest place and of the best days in American history."

We believe this to be a just estimate of Mr. Morse's greatness, and yet never was greatness veiled beneath so simple and unobtrusive and unasserting a form.

If men are known by the characters of those they attach to them by their own personal magnetism, then Mr. Morse stands on the highest grounds, for his life has connected him with the most illustrious characters of his age. In England, the Earl of Elgin, the Earl of Lincoln, Lord Brougham, the Marquis of Northampton, the chief Lords of the Admiralty, the officers of the Royal Society were all his friends. In Paris, Arago took him cordially by the hand, and, while yet a young man, working at his easel in the gallery of the Louvre, Humboldt was closely attached to him by the amenity of his manners and his intelligent appreciation of art. They frequently met at the house of Baron Gerard, whose soirees were attended by the most eminent artists of the Continent, and a warm friendship sprang up which grew stronger with years. At one of their interviews, Humboldt presented Mr. Morse with an engraving of himself upon which he wrote as follows:

"To Mr. S. F. B. Morse, whose philosophic and useful labors have rendered his name illustrious in two worlds. The homage of the high and affectionate esteem of

ALEXANDER HUMBOLDT."

The King of Denmark saluted him as a friend, and conferred upon him the decoration of the Order of "Danebroge." The Emperor and Empress of Russia received him with distinguished cordiality. Prince Esterhazy of Austria, the Emperor Napoleon and the chief men of the Continent, accorded him the closest personal attention and honor. The Sultan of Turkey decorated him with the diamond badge of *Nishan Iftichar*. Gold medals of scientific merit were awarded him by the Kings of Prussia and Wurtemberg and the Emperor of Austria. In 1856 the Emperor of the French presented him with the Cross of Chevalier of the Legion of Honor; and in 1858 the Queen of Spain conferred the Cross of Knight Commander of the Order of Isabella the Catholic. From the King of Portugal he received the badge of Knighthood of the Order of the Tower and Sword; and from the King of Italy the decoration of Knight of the Order of SS. Maurice and Lazarus. His friends in England were such men as Benjamin West, Fuseli, Northcote, Lamb, Coleridge, Southey, Rogers, and many of its nobility. There was a peculiar ease and gentleness in his manners which fitted him for the highest social spheres, and in his native land he has been a special subject of national regard, which, though without taking marked national expression, was yet very nearly allied to the power of personal affection.

To Dr. Adams' eloquent address we refer for a revelation of Mr. Morse as a christian man. He was his pastor and intimate friend. None knew him better or loved him more. It leaves us nothing to say on that subject.

We have only now again to express our gratitude in having been made the medium of an honor to Professor Morse, which touched his heart and brightened his last year of life. Only one thing marred that honor. Some papers stated that he was present at the inauguration of his own statue, and in Frank Leslie's fine picture of the scene, he is represented on the stand. Not so. His delicate sense of propriety kept him at home all day, until in the evening he appeared on the great occasion on which he bade so many of us a last and affectionate farewell.

As has been said in more than one of the resolutions offered at meetings throughout the country, Mr. Morse's life is an incentive to the young men of America, as an example of lofty aims and patient persistant endurance, and ultimate triumph. Let them imitate him in his gentleness, in his purity of character, in his broad acknowledgement of the labors of other men, in his genial, sunny, hopeful character, in his unfaltering christian faith. Let all of these characterize the staff of his great invention, and thus it may be said of him that "though dead he still speaketh."

So now, honored father and friend of so vast a family, so dear to us all, farewell. We shall trust to meet thee some coming day in the land where death has no sceptre and the cheek no tears.

THE LATE PROFESSOR MORSE—THE LESSON OF A LIFETIME.

The name of Morse has been so long among the great names of America that it has had a historical significance. And yet, now that we know the great inventor lies dead, we feel as if there was a wide gap in our national life. All the comforts and blessings that an earthly existence can give to the poor breathing body seem to have fallen to Morse. He lived long after the appointed time. His years were crowned with reverence and honor and fortune. He breathed the incense of that fame that so rarely comes to men in their own time. We are told that the sunshine of fame is always followed by the shadows of envy. It was the happy fortune of Morse to live into that calm, reverential, heaven-tinted twilight of old age, when even envy departs, and we feel at peace with our generation and with God.

We can realize how long Morse remained with us when we look over his life and the events with which he was contemporaneous. We speak of Shelley and Byron as we speak of Pope and Swift, as men who belonged to a far distant past. Yet Morse was an older man than Shelley, and but three years younger than Byron. He was a child when the Robespierres reigned; a lad at school before Napoleon won Marengo; a man in the flush and eagerness of life before he lost Waterloo. We are about to celebrate the centennial anniversary of our republic, and had Morse lived four years longer he could have taken part in the rejoicings as one who had lived under all of the Presidents. With his own eyes he has seen the republic grow from four millions to forty millions; from being an obscure, struggling nationality, to be one of the recognized Powers of the globe. In our own country he saw the rise of slavery, its triumph, its struggle and its fall. One after another he has seen America grapple with the social and political problems generated in this age of progress, and solve them and pass triumphantly on towards a splendid destiny. While America has slowly, surely, patiently, grandly moved on to this destiny, to a brightly opening future, full of duties and opportunities, he has seen revolution and change upturning the thrones and traditions of Europe.

Morse was, perhaps, the most illustrious American of his age. When we come to measure true greatness, how readily we pass from the confusing, barren echoes of what we call glory to what we might call usefulness! Looking over the expanse of the ages, we think more earnestly and lovingly of Cadmus, who gave us the alphabet; of Archimedes, who invented the lever; of Euclid, with his demonstrations in geometry; of Galileo, who solved the mysteries of the stars; of Faust, who taught us how to print; of Watt, with his development of steam, than of the resonant orators who inflamed the passions of mankind, and the gallant chieftains who led mankind to war. We decorate history with our Napoleons and Wellingtons. But it was better for the world that steam was demonstrated to be an active, manageable force, than that a French Emperor and his army should win the battle of Austerlitz. We have felt kindly to that philosophy which saw the consummation of human effort in the growing of two vines where one had grown before. For if war is valor and passion reduced to mathematics, how much better is peace, which gives valor and passion the exactness of algebra, and the wide, embracing scope of love and reason! "Peace," says Milton, "hath her victories no less renowned than war," and when a Napoleon of peace, like the dead Morse, has passed away, and we come to sum up his life, we gladly see that the world is better, society more generous and enlarged, and mankind nearer the ultimate fulfilment of its earthly mission, because he lived and did the work that was in him.

A man like Morse is a creation of that philosophy by which Bacon has so long governed the intellect of the world. In the same rank of heroes of peace we place Franklin, Fullerton and Stephenson. The newer inventions by no means dim the lustre of the old ones. Steam was the natural precursor of the telegraph. We had an agent which had shown how space could be controlled. Morse gave us an agency by which time was destroyed. If General Washington had been informed that man of the present time would sit in his seat while the words of an inaugural address were read on the Pacific long before the President had ceased to deliver it on the Atlantic; if he could have seen the United States and England united by a tie so subtle and so immediate in its effect that no war could sever it, he would have felt, that the mother country and her proud, imperial daughter, were united by a tie which no war and no revolution could sever. We have seen science nullify war. We are nearer Great Britain to-day in all that constitutes a nation's happiness, more closely concerned with the politics, the literature, the social joys and pleasures of her people, than before the Revolution. War divides nations; science unites them and carries out in silence and certainty the Divine decree, which seems to will that the nations shall come more closely together, and that the children of men shall become as it were of the same family.

If these achievements are the fulfilment of the higher destinies of mankind, then Franklin and Fulton and Stephenson belong to the highest rank of heroes. They are the masters after all. How much more truly may the same be said of the illustrious American who was gathered to his fathers yesterday evening! The story of his life is told elsewhere. The results of his life are known to all men. The lesson we gather from it is as old almost as human genius and human ambition. Effort, disappointment, derision, detraction, envy, strife, that deferred hope that maketh the heart sick, weariness, fainting by the way, almost despair—is it not written again and again in the history of men who are called upon to serve their fellow-men? Do we envy those who win the fame and glory of Morse? Let us think of the others who had perhaps this heaven-inspired and far-reaching spirit, and who failed in their struggles. When we see the argosy, laden with the stuffs and gems and spices of the East, and think of her angry voyage and the safe arrival in port, should we not think of those who sailed amid breezes as auspicious only to shiver and rend and sink? We honor Morse because he succeeded. We are told that the worship of success is selfishness, and that generous appreciation would honor as highly the men who dared nobly only to fail. When men who succeeded as Morse, suffer as he did, we can feel that their triumphs were fully earned. We see in this man's life what can be done by patient, resolute endeavor, courage, cheerfulnes, belief in his mission. Let others sing the glory of his achievements and descant upon his services to the world—his honors, his possessions, his ripe and reverend years—the rare blessings that crowned and capped his life. We see in his career the success that patient merit will always win when sustained by honor and courage. The life of Morse is full of lessons; but this, if we learn it truly, is the most precious of them all.—*N. Y. Herald.*

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
April 15, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since April 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

145	Acton, S. C.	66	Nesquehoning, Pa.
319	Belle River, Ill., re-opened	*	Ossipee, N. H.
84	Beavertown, Pa.	52	Odenwelder, Pa., check Easton, Pa.
253	Batesville, Ind.		
456	Blocks, Mo.	480	Oakwood, Texas
140	Catfish, Pa.	66	Penobscot, Pa., heretofore an Other Line office
294	Columbiana, Ala., re-op'd		
66	Coalport, Pa., check Mauch Chunk, Pa.	84	Painter, Pa.
		66	Rockport, Pa., heretofore an Other Line office
*	East Wakefield, N. H.		
270	Edwardsburg, Mich.	66	Solomons Gap, Pa., check Penobscot, Pa.
58	Gardners Switch, Pa.		
87	Garysburg, N. C.	66	So. Wilkesbarre, Pa., check Wilkesbarre, Pa.
219	Goodmans, Fla.		
66	Leslies Run, Pa., check White Haven, Pa.	58	Spring Brook, Pa., heretofore an Other Line office
46	Milford, Pa., heretofore an Other Line office	66	Silver Brook, Pa.
		336	Toulon, Ill,
84	Middleburg, Pa.	318	Tuscola, Ill.
84	McClure, Pa.	66	Tamanend, Pa.
397	Mt. Sterling, Iowa	*	Wakefield, N. H.
151	Martins Ferry, O.	66	Walnutport, Pa., check Lehigh Gap, Pa,
47	Morrisville, Pa.		
58	Mill Creek, Pa., heretofore an Other Line office	*	West Ossipee, N. H.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.	*Leaves this Line.*
East Wakefield, N. H.....	25 2	Great Falls, N. H.
Ossipee, N. H.....	25 2	"
Wakefield, N. H.....	52 2	"
West Ossipee, N. H.....	25 2	"

OFFICES CLOSED.

Blakely, Ala.; Big Cabin Creek, Ind. Terr.; Keechie, Tex. and Montezuma, Ga.

GENERAL INFORMATION.

The following is a revised list of offices on the Mo. River, Tel. line with "tariff for Other Lines," from Sioux city, Iowa:
Elk Point, Dac..... 45 and 5 Springfield, Dac.....125 and 10
Fort Randall, Dac,..200 and 15 Vermilion, Dac..... 65 and 8
Fort Scully, Dac....300 and 20 Yankton, Dac.....100 and 10

The Missouri River Tel. Co. make no charge on government business on their line, consequently on this business the W. U. government rate, to or from Sioux City, only should be collected.

Business for Fort Ellis, Mont., may be taken and sent to Boseman, Mont., from which point it will be mailed; also, business for Camp Baker, Mont., may be sent to and mailed from Helena, Mont.

On and after May 1, "Half-rate" messages will be taken for and received from St. John, N. B., and Halifax, N. S.

The P. O. adds. of Cornwells, Pa., is Andalusia, Pa., and that of Goldsboro, Pa., is Etters, Pa.

The square for Cherokee, Ks., will hereafter be 467 instead of 457.

Saugatuck and Westport, Conn., are one and the same place, messages and letters should be addressed Saugatuck, Conn.

Townsend, Del., will hereafter be checked direct.

ATLANTIC CABLE BUSINESS.

We are informed that telegraph communication is now open with the following islands in the Grecian Archipelago, and to seaports in Turkey, in Asia:

The messages are forwarded via. Falmouth.

London to		*Twenty words.*
Greek Islands.	Crete, Canea, Retimo,	$6 62
	Cyprus,	6 00
	Mytilene, Rhodes, Samos, Scio,	5 75
Turkey in Asia Seaports.	Marmorice, Latakia, Scalanova,	5 38

Half-rate for every additional ten words, or fraction of ten words.

Hereafter, all messages for China and Japan, will be forwarded by either the Falmouth or Russian lines, unless otherwise specially directed by the sender.

The rates by those routes are the same as now in force, with the exception that the tariff to Nagasaki, Japan, by the Russian route, is raised to $26.50, to correspond with that of the Falmouth cable.

If senders require messages to be forwarded by other routes, the words "Via Teheran," or "Via Turkey," must be inserted and paid for, and the ordinary continental rates charged, viz:—To Hong Kong, $35.00; to Shanghai, $41.25; to Nagasaki, $46.25.

WILLIAM ORTON, Pres't,

DEAD!

Stat Magni Nominis Umbra—In Memoriam Professor S. F. B. Morse.

BY ROSA VERTNER JEFFERRY.

Thrill it down the electric wire,
Far and near, to town and mart;
Flash that word in prisoned fire
Through the world's enlightened heart;
Where the pallid North reposes,
Where the avalanche is born;
Whisper it unto the roses
Blushing round the "Golden Horn;"
Send it South from Scotia's mountains—
From her eagle's misty nest—
To the spray of Persian fountains,
Breaking on the bul-bul's breast;
From the Alpine torrents seething,
Thrill it—dumb amidst their swell—
To the amorous zephyrs breathing
Through Italia's "golden shell;"
Go where Spring her pale bloom nurses;
Flash it down the Russian steeps
To red Vesuvius, muttering curses
By Campania's purple deeps;
To the royal Adriatic
Venice on her ocean throne—
And through spice-groves aromatic,
Southward to the torrid zone!
He has written us a story
On the earth in pulsing lines
From our northlands, bleak and hoary,
To where the blue Marmora shines,
Through the deep track of the ocean,
Flashing past the coral isles,
Viewless, voiceless, without motion,
Thrills his fame down countless miles.
On to Oriental Cairo,
Past that waste where Egypt flings
Her glory from the tomb of Pharaoh,
A gauntlet unto living kings—
Where broods her ancient sphinx, abashing
Modern problems to the last
He sends a present wonder, flashing
Defiance at the stony past!
Men of every faith and nation
Honor, love, revere, admire
One who sought not adulation
When he chained the electric fire;
Who, discouraged and defeated,
Bore it with a patient grace;
By no boastful pride elated,
When he conquered time and space.
Faithful spirit, all undaunted,
Toiling, undismayed, for years,
Till along the wires enchanted
Greetings joined two hemispheres!
Then! all earthly praise despising,
With one holy, prayerful thought,
His fiery servant thus baptizing—
"Mark ye what the Lord has wrought!"—
Fervent hallelujah springing,
Breathless down the electric vein.
Mighty mind!—those wires are winging
Now through earth one sad refrain,
"The master's dead,"—their wail is flying
"Ye shall see his like no more!"
North winds sob to south wind dying
On the Byzantian shore!
Down the iron vein it shivers,
Potent, fervid, burning stream!
On through forests, deserts, rivers,
Passing time, and winds, and steam!
Subtle, flameless, harmless fire,
The wail of nations down it springs
So silently, that on the wire
Wild birds perch and plume their wings!
He had lived a great magician
In the dark and heathen age;
Lights that scatter superstition—
Faith and science—call him "sage."
Sage and hero, loved of nations
Lo! thy dauntless soul has found
The lightning's mystic habitation,
Where its lurid bolts are bound!
Couldst thou send a message thrilling
Earthward, it would be once more
"Eureka"—"on! your task fulfilling;
In God's name, Excelsior!"

LEXINGTON, KY., April 6, 1872.

SENATOR FRELINGHUYSEN has introduced a bill in the United States Senate to facilitate telegraphic connection between Asia and America.

WESTERN UNION TELEGRAPH COMPANY, Wednesday, April 3d, authorized the issue of bonds of the Company, for $1,500,000 to meet the remaining instalments of the purchase money of real estate bought by the Company at the corner of Dey street and Broadway, and for the erection of a building thereon.

LONDON, April 9.—A circular is issued inviting subscriptions for 45,000 shares in the Great Western Telegraph Company, which proposes to lay telegraph cables direct from England to New York, and thence to the West Indies. The shares are twenty pounds sterling each. The total capital of the company is fixed at £1,350,000. The Hoopers will make and lay the cable for £1,330,000

THE cable announces that final arrangements have been made by the French Atlantic Cable Co. with the London Telegraph Maintenance Co. for the laying of a fourth Atlantic cable, the prospectus of which will be immediately issued. It is designed to lay this cable with the termini at Milford Haven, on the coast of Wales, and Rye Beach on the coast of New Hampshire. This cable is to be laid in anticipation of future necessities, or in the experiment of reduced rates of charge. The present cables are forwarding with ease all the business at present offered.

WE have had placed upon our desk, by an excellent young lady, on behalf of the Ladies' City Department, 145 Broadway, N. Y., a most superb bouquet of fresh flowers, the odors from which speak of the kindness which led to the presentation of this very unexpected gift. It was accompanied with the following pleasant note:

DEAR SIR.—In several instances you have, very kindly, remembered the ladies of the City Department, each time your kindness being appreciated by us all.

Please accept, with our compliments and good wishes for your future happiness and prosperity, the accompanying basket of flowers from THE LADIES OF THE CITY DEPARTMENT.

So you see we have had our reward. The lips of the reverend old man whom we kissed for these ladies last summer, are now cold in death, but the affectionate salutation is returned to us in living flowers, which we accept with great delight, happy if, in anything we have done, we have duly merited them.

TO MEET any desire which may exist to have a likeness of Professor Morse, we offer to send three good engravings of him to one address, on roller, post paid, for twenty-five cents.

IN *Les Mondes* we find a proposed plan for replacing the oil signal-lamps of ships by an electric light derived from a magneto-electric apparatus, set in motion by a screw which is rotated by being drawn through the water by the ship.

WE have to thank Mr. H. N. Drury, of the Western Union Telegraph Office, Burlington, Vt., for a splendid brick of maple sugar. Mr. Drury was sweet, also, on Gen. Eckert, Mr. Prescott, and Mr. Abel, each of whom received a sacharine brick like our own. A sweet man is Mr. Drury.

THE SERVICE.

THE FATHER OF THE TELEGRAPH.

New York, April 2.—Professor Morse died at seventeen minutes before eight this evening.—[Telegraph.

If it is legitimate to measure a man by the magnitude of his achievements, the greatest man of the nineteenth century is dead. Some days ago the electric current brought us the intelligence that S. F. B. Morse was smitten with paralysis. Since then it has brought us the bulletins of his condition as promptly as if we had been living in the same square, entertaining us with hopes which the mournful sequel has proven to be delusive; for the magic wires have just thrilled with the tidings to all nations that the father of telegraphy has passed to the eternal world. Almost as quietly as the All-seeing eye saw the soul depart from that venerable form, mortal men, thousands of miles distant, are apprised of the same fact by the swift messenger which he won from the unknown—speaking, as it goes around its world wide circuit, in all the languages of earth. There is something peculiarly suggestive in this mysterious element, simultaneously penetrating the newspaper offices, the exchanges, the legislative halls, the courts and the cabinets of all nations, to whisper the mournful news that the benificent genius to whom it owes its introduction among men, has faded into the unknown world from which he rescued itself, and vanished from earth forever.

Letters came to the aid of the individual mind and increased its energies by extending the circle of hearers, and propagating its utterances through succeeding generations. But the grand supplement of Professor Morse has made the world a neighborhood. Letters defied time; the telegraph has annihilated both time and space. It leaps across the expanse of the ocean with its message as easily as if it were a brook. Not fatigued by climbing mountains and traversing thousands of miles in its journey, it crosses a continent on its errand as quickly as another messenger would cross the street.

To Americans the telegraph possesses the special significance of making that form of government practicable for a continent which has hitherto been available only for cantons or cities, by means of bringing remote sections into practical every-day intercourse, and into familiarity and homogeneity. Antecedent history does not record a single instance of a successful republic on a large scale. The arch has been found to be weak. But, now however, and without entering further into the subject, let it suffice to say that, if a republican form of government is practicable for a city or canton, the magic of telegraphy has made it equally o for a confederation of populous States.

To appreciate the inventor we must appreciate the invention. We have, therefore, enumerated a few of its wonderful achievements and faculties. Its influences upon the world are merely beginning to develop, as its uses, conveniences and improvements are only beginning to unfold. When telegraphy was in its earlier infancy, the world, with more than its usual justice, hastened to crown the great inventor with distinctions and honors. Prussia, France, Wurtemberg, Austria, Denmark, Spain, England the United States, and even Turkey, testified their appreciation of his services to mankind by gifts of money and badges of distinguished knightly orders. Though this invention affords another marked illustration of the parallelism of contemporary minds—two other inventors having made simultaneously near approaches to Morse's discovery—yet, in the estimation of the world at large, none divided his honors with the immortal American. The same remarkable fact attended the discoveries in electricity by Dr. Franklin; and as mankind have readily conceded that the earlier sage may justly claim the merit of bringing the lightning down from the heavens, it will be even more frankly admitted that Morse may claim the honor of seizing and binding it in the service of men.

Professor Morse took no royal road to this discovery. Indeed, it is never a characteristic of genius to seek such roads. He was dependent necessarily upon facts and principles brought to light by similar diligent, patient minds, which had gone before him. Volta, Galvoni, Morcel, Grave, Faraday, Franklin, and a host of others had laid a basis of laws and theories upon which he humbly and reverently mounted and arranged his great problem for the hoped-for solution. But to him was reserved the sole, undivided glory of discovering the priceless gem, "richer than all its tribe," which lay just beneath the surface, and around which so many *savans* had vainly and blindly groped.

He is dead, but his mission was fully completed. It has been no man's fortune to leave behind him a more magnificent legacy to earth, or a more absolute title to a glorious immortality. His was a life such as to awaken the passionate enthusiasm and plaudits of the multitude, as it was a life somewhat sequestered, and altogether devoted to a task which lay in the cold, unsympathetic domain of natural science. There is no doubt, however, that to the honor of being one of the most distinguished benefactors of the human race, he added the personal and social graces and virtues of a true gentleman and a Christian philosopher. The memory of his private worth will be kept green amid the immortelles of sorrowing friendship for a lifetime only, but his life monument will endure among men as long as the human race exists upon earth.—*Courier-Journal, Louisville, Ky.*

TELEGRAPHERS' MUTUAL LIFE INSURANCE ASSOCIATION.

On the election of Mr. A. S. Brown to the Treasurership of the Telegraphers' Mutual Life Insurance Association, we addressed him the following letter, which we give for the information of all concerned.

New York, April 1, 1872.

A. S. Brown, Esq., Treasurer elect, &c.

Dear Sir:—It is pleasant to me to know that the Association, with so much heartiness and unanimity, have elected you to succeed me. They could not have selected one in whose hands their interests will be more secure, or under whom the designs of the Association will be more fully carried out.

At this date there have been 1512 Certificates issued, and 29 Assessments called. With this large membership it seems somewhat disappointing to find that probably 700 of these are either dead, resigned, too poor, too unsteady, or otherwise withdrawn from the Association. Much of this was, indeed, to have been expected. Young men are constantly entering new pursuits, and regard themselves thus cut off from telegraphic bonds. Young women marry, and drop their membership. Many change their residence, and notices do not reach them. The difficulty and cost of remittance also has caused a large number to resign. When District Treasurers are appointed in the several States it will remove one large cause of the difficulties which have been in the way of its growth, and will secure a steadier and better satisfied membership.

The following is the condition of the Treasury as it now passes to your hands, minus whatever interest may meanwhile have accrued:

Balance at credit of expense acc't Nov. 1, '71,	$340 38
256 certificates, 50c. each, to expense acc't,	128 00
From new certificates yet unpaid to heirs.	131 00
On hand for Assessment No. 25,	746 00
" " " 26,	705 00
" " " 27,	674 00
" " " 28,	79 00
" " " 29,	39 00
" for advance assessments,	55 00
	$2,897 38
By printing new certificate books, envelopes, &c.,	$49 30
Desk for Secretary,	30 00
Postage stamps,	14 00
Assistance,	20 66
New books of entry, envelopes, &c.,	33 00 146 96
At your credit,	$2,770 42

RECEIPTS FOR ASSESSMENTS NOT YET CALLED.

C. A. Thomas, Aspinwall, 30 31 32 33	4 00
	$55 00

The accumulation of money shown by this statement has been caused, as you know, by the rapidity with which one death has followed another during March, and the incomplete state of the assessment delaying any possible settlement with heirs. The time fixed by the Board for settling claims, sixty days after making the assessment, will expire in the case of assessment No. 25 with April 8th, it having been issued about February 8th, and will be payable to the heirs of George Henry Patriquin, of Port Hastings, Cape Breton. Assessment No. 26, payable to the heirs of Naylor L. Brown, of Athens, Tenn., will be due a month later, and which will give time to secure, we trust, a number of payments as yet withheld. Many will no doubt feel discouraged at the recent mortality, but any one noticing the average of the year will easily see that the year's payments are not more than at most one-third of the cost of insurance in the cheapest of Insurance Companies, and is besides a source of brotherly help which should be loyally maintained aside from any personal advantages which might accrue from its membership.

Hoping that under your good guidance the Association will greatly enlarge its usefulness, and with an affectionate farewell to you and all the widely scattered memberhood to whom I have come to feel attached as a brother and friend, believe me,

Yours sincerely,

James D. Reid.

WE have had the pleasure of a visit of Mr. Cyrus A. Thomas, Telegraph Superintendent at Aspinwall, who, after four years' constant service in that sunny region, has come North to recruit. Mr. Thomas reports great activity in South American telegraphs where all the populations are thoroughly awake to the importance of telegraphic connection between their own ports and centres of commerce, and other nations. A line of 300 miles is being built by Mr. Stanley McNider, an old Canadian operator, connecting the capital of Salvador with the ports of La Union and Libertade, by one of the best built lines to be found anywhere. In Guatemala, also, extensive lines are in progress.

NOTHING NEW UNDER THE SUN.

Humboldt, in his *Cosmos*, states that the Chinese had magnetic carriages with which to guide themselves across the great plains of Tartary, one thousand years before our era, on the principle of the compass. The prototype of the steam engine has been traced to the æolipyle of Hero of Alexandria. The Romans used movable types to mark their pottery and indorse their books. Mr. Layard found in Nineveh a magnifying lens of rock cristal, which Sir D. Brewster considers a true optical lens, and the origin of the microscope. The principle of the stereoscope, invented by Professor Wheatstone, was known to Euclid, described by Galen fifteen hundred years ago, and more fully in 1599 A. D., in the works of Baptista Porta. The Thames tunnel, thought such a novelty, was anticipated by that under the Euphrates at Babylon; and the ancient Egyptians had a Suez Canal. Such examples might be indefinitely multiplied, but we turn to photography. M. Jobard in his *Nouvelles Invention aux Expositions Universelles*, 1857, says a translation from German was discovered in Russia, three hundred years old, which contains a clear explanation of photography. The old alchemists understood the properties of chloride of silver in relation to light, and its photographic action is explained by Fabricius in *De Rebus Metallicis*, 1566. The daguerreotype process was anticipated by De la Roche in his *Giphantie*, 1760, though it was only the statement of a dreamer.

WE have a number of complaints from parties who have remitted money to Messrs. Harvey & Dow, St. Johnsbury, Vermont, for badge-pins. Some of these we forwarded, asking the reason why orders were not filled. Receiving no reply, we withdrew the advertisement. We now have a communication from them, dated Lyndonville, Vt., which may explain the difficulty, and of which we hope soon to learn.

BORN.

LUDWIG.—February 20th, at 4 A. M., to Mrs. E. F. Ludwig, a daughter.

HOTALING.—To B. S. Hotaling, Manager W. U. Tel. and Agent Missouri, Kansas and Texas Ry., Chetopa, Kansas, a son, only an eight pounder, but a very good sounder. "'Rah for Ben."

SHAUTZ.—On the 27th of March, 1872,, to W. N. Shautz, Manager W. U. Telegraph Office, Blandon, Pa., was born a son, the fourth in 4 years, and all No. 1 sounders.

MARRIED.

LANE—PERSON.—On the 9th inst., by Rev. Gregory, at Middletown, Mr. Andrew Lane, Manager W. U. Office, to Miss E. A. Person, of Middletown. No cards.

HUNT—LAWSON.—On Tuesday evening, at the residence of the bride's brother, Fountain, Ind., by Rev. Morris Boatman, Mr. Harry C. Hunt, of Indianapolis, Ind., Agent and operator Indiana and St. Louis R. R., Fountain, Ind., to Miss Ollie A. Lawson, of Fountain, Ind. No cards.

SMITH—AUNGST.—On Wednesday, April 3d, at the residence of the bride's father, Decatur, Ill., by Rev. J. H. Noble, J. Manlove Smith, W. U. Telegraph, Rock Island, to Fidelia Aungst.

DIED.

BROWN.—Elliott H. Brown, Operator New York City, died at his parent's residence, Binghamton, N. Y., of rapid consumption, April 2, 1872, in the 24th year of his age.

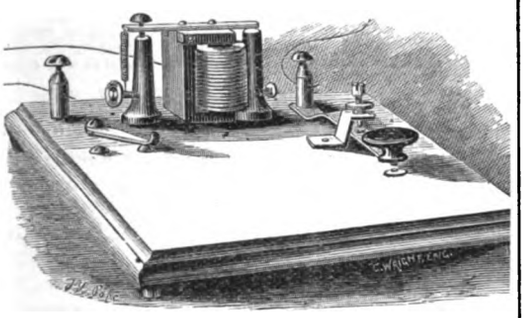
A BOY'S RECOMMENDATION.



A gentleman advertised for a boy to assist him in his office, and nearly fifty applicants presented themselves to him.

"I should like to know," said a friend, "on what ground you selected that boy, who had not a single recommendation?"

"You are mistaken," said the gentleman, "he had a great many. He wiped his feet when he came in, and closed the door after him, showing that he was careful. He gave up his seat instantly to that lame old man, showing that he was kind and thoughtful. He took off his cap when he came in, and answered my questions promptly and respectfully, showing he was polite and gentlemanly. He picked up the book which I had purposely laid upon the floor, and replaced it on the table, while all the rest stepped over it or shoved it aside, and he waited quietly for his turn, instead of pushing and crowding, showing that he was honest and orderly. When I talked with him I noticed that his clothes were carefully brushed, his hair in nice order, and his teeth as white as milk; and when he wrote his name, I noticed his finger-nails were clean, instead of being tipped with jet, like that handsome little fellow's in the blue jacket. Don't you call those things letters of recommendation? I do, and I would give more for what I can tell about a boy by using my eyes ten minutes than all the letters he can bring me."

THE NONPAREIL TELEGRAPH APPARATUS.

(Patent applied for.)

This apparatus supplies a want which has long been felt, viz.: that of a SIMPLE and CHEAP

MORSE TELEGRAPHIC INSTRUMENT,

with all the necessary Batteries and other appurtenances in a CONVENIENT and COMPACT form.

By means of a switch, which is now placed on each instrument, they can be worked as desired, either as the open or the ordinary continuous, or closed circuits.

It is intended especially for the use of

STUDENTS, AMATEURS, AND OPERATORS,

but will be found to be equally well adapted for use on

PRIVATE TELEGRAPH LINES,

or Short Lines of any description, which are not over three or four miles in length.

A NEW FORM OF BATTERY

is employed, which is compact, efficient, and economical, and especially adapted to the purpose for which it was designed. Each instrument will be accompanied by a

BATTERY, CHEMICALS, INSULATED WIRE for connections, together with an

ILLUSTRATED BOOK OF INSTRUCTIONS,

which in itself forms a complete elementary treatise upon the ART OF TELEGRAPHY.

PRICES:

Single Instrument, complete, with Batteries, etc.....$8 00
Two Instruments, " " " " 15 00

Sent by Express on receipt of price.

Remittances may be made by Post Office Order, Registered Letter, or Draft payable to our order. Persons ordering Instruments will please write plainly, giving Post Office, County, and State, with instructions for shipment. Address,

F. L. POPE & CO.,
P. O. Box 6010. 80 Broadway, (Room 51,) New York.

THE NONPAREIL TELEGRAPH APPARATUS may be procured through the leading dealers in Telegraph Supplies throughout the country.

SEND FOR A CIRCULAR.

16,000 MILES

OF

"JOHNSON'S" WIRE

USED BY THE

TELEGRAPHS OF THE UNITED STATES

DURING THE YEAR 1871.

This is sufficient refutation of all the intimations thrown out by the Manufacturers and Importers of other Wires, reflecting upon the acknowledged superiority of the Wire manufactured by

Messrs. RICHARD JOHNSON & NEPHEW,

MANCHESTER, ENGLAND.

Their Works are the Largest in the World.

The great advantage which they possess over other manufacturers is their patent process of drawing Wire in great lengths (averaging 1,200 feet).

All Telegraphers know that, in nine cases out of ten, breaks in Wire occur at joints, hence the less joints the fewer breaks.

Messrs. RICHARD JOHNSON & NEPHEW furnish three-fourths of all the Telegraph Wire used by the

ENGLISH GOVERNMENT.

This Wire is necessarily subject to the tests, etc., imposed by the English Post-office Department.

A large stock always on hand and for sale at the lowest market prices—both free and in bond.

AMERICAN FIRE ALARM

AND

POLICE TELEGRAPH.

GAMEWELL & CO., PROPRIETORS,

NO. 104 CENTRE STREET, NEW YORK.

J. W. STOVER,
General Agent and Superintendent.

L. B. FIRMAN, Chicago, Ill.,
General Agent for the West and North West.

J. R. DOWELL, Richmond, Va.,
Special Agent for Virginia and North Carolina.

J. A. BRENNER, Augusta, Ga.,
Special Agent for Georgia and South Carolina.

L. M. MONROE, New Canaan, Conn.,
Special Agent for New England.

This system of Fire Alarm and Police Telegraph, with a Central office, or upon the

AUTOMATIC PLAN,

is now in operation in the following cities, to which reference is made for evidence of its great SUPERIORITY, VALUE and UNIFORM reliability:

Albany, .N Y.,	New Orleans, La.,
Alleghany, Pa.,	New Haven, Conn.,
Boston, Mass.,	Newark, N. J.,
Buffalo, N. Y.,	Omaha, Neb.,
Baltimore, Md.,	Philadelphia, Pa.,
Chicago, Ill.,	Pittsburg, Pa.,
Cincinnati, Ohio,	Portland, Me.,
Columbus, Ohio,	Peoria, Ill.,
Cambridge, Mass.,	Providence, R. I.,
Charlestown, Mass.,	Quebec, L. C.,
Covington, Ky.,	Rochester, N. Y.,
Detroit, Mich.,	Richmond, Va.,
Dayton, Ohio,	Indianapolis, Ind.,
Elizabeth, N. J.,	St. Louis, Mo.,
Fall River, Mass.,	St. John, N. B.,
Fitchburg, Mass.,	Springfield, Mass.,
Hartford, Conn.,	San Francisco, Cal.,
Jersey City, N. J.,	Savannah, Ga.,
Louisville, Ky.,	Syracuse, N. Y.,
Lawrence, Mass.,	Troy, N. Y.,
Mobile, Ala.,	Toledo, Ohio,
Montreal, Canada,	Toronto, Canada,
Milwaukee, Wis.,	Washington, D, C.,
New York City,	Worcester, Mass.,
Lynn, Mass.,	New Bedford, Mass.,
Lowell, Mass.,	Bridgeport, Conn.

The distinctive features of these systems of

FIRE ALARM AND POLICE TELEGRAPHS,

ARE,

First—The AUTOMATIC SIGNAL BOXES, the simple electro-mechanism of which enables any one—even a child—to give an *instantaneous*, *general*, and *definite* alarm of fire.

Second—The AUTOMATIC REPEATER, through which the apparatus may be distributed in a combination of circuits, and the entire system successfully worked without the constant personal attention of either operators or watchmen.

Third—The ELECTRO-MECHANICAL BELL STRIKERS, adapted to produce the full tone of the largest church or tower bells.

Fourth—The ELECTRO-MECHANICAL GONG STRIKER, for hose and engine houses, by means of which the location of the fire is instantaneously communicated to the members of each fire company.

These features combined form the

ONLY PERFECT, COMPLETE, AND RELIABLE SYSTEM

OF

FIRE ALARM TELEGRAPH IN THE WORLD.

Messrs. GAMEWELL & CO. are the owners of the original *FARMER AND CHANNING PATENTS*, one of the most important of which has just been extended for seven years. During the past seventeen years they have spared no expense or effort to secure improvements, and the systems are now covered by

MORE THAN TWENTY PATENTS.

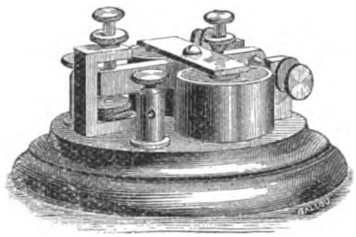
The introduction and operation of the

AUTOMATIC SYSTEM

involves so little expense, compared to the benefit which it confers, that even small communities can profitably adopt and maintain it.

The co-operation of TELEGRAPHERS in securing its introduction into their localities is cordially invited, and their efforts will be duly appreciated and compensated.

Any information desired in regard to the above system will be cheerfully and promptly furnished upon application at the office.



A pamphlet setting forth more fully its advantages and superiority, has been printed, and will be supplied to Municipal Authorities and others interested in Fire Alarm and Police Telegraphy upon application as above.

MECHANICAL TELEGRAPH INSTRUMENT

PATENTED MAY 31st, 1870.

For Students, Colleges, &c. No battery required. An ordinary key and sounder is placed upon a proper base. The sounder is moved by a lever under the base, connected with the key, making a perfect instrument for those wishing to learn the Art of Telegraphy. An expert could not tell, without examining it, that the instrument was not worked by a battery.

It should be introduced into every school and family where there are those who wish to learn the Art.

Hundreds of persons throughout the country desire to become expert Telegraphists, and are constantly seeking permission to practice in the various telegraph offices.

This instrument is an outgrowth of this pressing demand. The Inventor is himself a practical operator, now in active service. Operators and others wishing to teach or learn the Art, will be delighted with this instrument.

It can be placed anywhere, as it does not occupy a space more than six inches square.

Its cost is but $7, and there is no expense whatever to keep it constantly in working order.

We will send a copy of SMITH'S MANUAL, free of charge, with each instrument, to individuals or clubs. The instructions in this Manual are particularly adapted to those who wish to learn by sound.

Special and liberal terms to manufacturers.

Remittances can be made by certified draft on New York, Cleveland, or Pittsburgh, money by express, charges paid, post office order, or registered letter at our risk.

Parties ordering instruments, from points except well-known cities, will please give the name of county and State.

Price, $7. Silver Plated, Extra Finish, $10.

Address, D. W. PUTT & CO.,

These instruments can also be procured at the same price from L. G. Tillotson & Co., New York; Bliss, Tillotson & Co., Chicago, Ill.; Chas. Williams, Jr., Boston, Mass.; M. A. Buell, Cleveland, O.

WIRE IN BOND.

For the accommodation of the
SOUTH AMERICAN, CUBAN and MEXICAN TRADE,
we shall hereafter keep a stock of the Celebrated

"JOHNSON" WIRE,

both plain and Galvanized, in Bond, ready for shipment from New York.

PRICES AS FOLLOWS:

No. 9, Plain Annealed	4½ cts. Gold.
No. 9, Galvanized	5¼ "
No. 8, Plain Annealed	4¾ "
No. 8, Galvanized	5 "

This Brand of Wire is the best in the world, and has been adopted exclusively by the Western Union and many other Telegraph Companies.

We also continue to import this Wire for use in this country, notwithstanding the high rate of duty imposed by Congress in the interest of the monopolists. Any amount of it can be seen at our store at all times. The import duty on wire is now two cents per lb. gold, and 15 per cent. *ad valorem*.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 11. NEW YORK, MAY 1, 1872. WHOLE NO. 108.

THE NEW YORK SWITCH BOARD.

The accompanying cut represents a part of one section of the new switch in the New York office. The switch is divided into three sections, intended respectively for the Eastern, Southern and Western circuits. Each section makes provision for accommodating forty-four main wires, or one hundred and thirty-two in all, with any desired number of loops, instruments and batteries. The whole switch is twelve feet in length by three feet in height, and contains sixteen thousand pieces. In each section of the switch there are forty-four vertical metallic strips, to which the main wires are attached. Between each two metallic strips is placed a row of metallic buttons, to which are attached the batteries. On the left hand of the switch board, it will be observed, the buttons are numbered from one to twenty, consecutively. All the buttons on the same horizontal line are connected together at the back of the switch by means of a copper wire. Small circular holes will be seen in the cut on both sides of each button, and in the corresponding portions of the vertical metallic strips. These are designed for connecting the button and the strip together by means of a small metallic peg. Immediately beneath the lower end of the vertical strips are placed a corresponding number of spring-jacks, and beneath these again still another series of spring-jacks. Into the upper series of spring-jacks are inserted wedges, to which are connected wires leading to the instruments, and into the lower series of spring-jacks are inserted wedges to which wires are attached connecting with special batteries. Each spring-jack bears an ivory plate, upon which is engraved the number of the circuit to which it is attached. The vertical metallic strips, buttons and spring-jacks are handsomely nickel-plated.

The diagram beneath the table upon which the switch rests, shows how the connections are made. In this diagram the positive pole of the battery is represented as being connected with the button A, a wire in the rear connecting A with A'. The main line wire is represented in the diagram as connected with E, which is the upper spring-jack referred to. At D, is inserted a wedge connecting by insulated wires with the operating instruments. At C, the lower spring-jack is represented in which is to be inserted, when necessary, the special batteries or loops. The wire F, connects the lower spring-jack with the vertical metallic strip 1, and by inserting the peg G, in the circular orifice between the button A, and the strip 1, the line wire is conneeted through the battery "to earth."

Each section of the switch is built of mahogany, cut in strips two inches wide by one inch thick, and separated from each other by a space of one-eighth of an inch, to prevent injury to the brass work by shrinkage. Each piece of mahogany supports two strips of brass and one row of discs or buttons. The spring-jacks are held in position by stout spiral wire springs attached to the back of the switch.

There are now working from this switch two hundred and one wires, namely:—main wires to the east, twenty-two; to the west, twenty-eight; to the south, thirty-nine; branch wires and loops, one hundred and twelve.

There are connected to the round plates in front the following general batteries: 4 of 45 cells, 1 of 40, 2 of 30, 1 of 28, 2 of 25, 1 of 15 and 1 of 8.

LISBON TO BRAZIL.

A convention has been signed between the Maintenance and Construction Company of Great Britain and the government of Portugal, for the laying of a telegraphic cable from Lisbon, by way of the Madeira and Cape Verde Islands, to Brazil. This is a great undertaking; but the company indicated is a strong one, and will doubtless carry the enterprise expeditiously through. Between Lisbon and the nearest point on the cost of Brazil, Cape St. Roque, by the route designated, the distance is some three thousand five hundred miles, in a southwesterly direction. For the first two thousand miles, by the Madeira, Canary and Cape Verde Islands, the line, a few hundred miles distant, will run parallel with the west coast of Africa. The Cape Verde Islands are within two days by steam from the British settlement of Sierra Leone and our neighboring African republic of Liberia. From Sierra Leone, across the Atlantic to Cape St. Roque, in Brazil, the distance is nearly the same as from the most southerly of the Cape Verde Islands, about fifteen hundred miles. But on the route between these islands and Cape St. Roque are first, the little island of St. Paul, and then, within two hundred miles of said Cape, is the little island of Fernando Noronha; so that, from these convenient stations, *en route*, no single stretch of the cable between Lisbon and Brazil exceeding eight hundred miles will be required.

The advantages offered to the company and to Great Britain and its nation of shop-keepers, from the laying of this cable, are broadly suggested in the immense and constantly increasing trade between Brazil, the Argentine, and other South American States, on the one hand, and England on the other. The facilities which the cable will afford in the timing of exchanges and shipments of goods need not be mentioned. This cable will unquestionably operate to systematize and extend in every direction the commercial exchanges of England with the South American States. And again, this line from the Cape Verde Islands will contribute its advantages to the British establishment at Sierra Leone, and to its railway intended to capture the great interior trade of Timbuctoo, and to the various other English commercial enterprises afoot in equatorial Africa. Nay, the conveniences of this cable will be felt at the Cape of Good Hope, and will thence extend to the new and prosperous British colony of the African diamond fields.

Digitized by Google

The advantages suggested to the United States from this cable are of a secondary character; but still we shall not be loosers by it unless our commercial people choose to lag behind hereafter as they have done heretofore in the competition for the illimitable traffic of South America. States.—*N. Y. Herald.*

THE NEW YORK FIRE ALARM TELEGRAPH.

A visitor to the central office in Mercer street is surprised at the amount of delicate and costly machinery which is crowded into the small room devoted to the use of the telegraph. Three sides of the apartment are completely filled with the apparatus—some of it so intricate that it must be kept covered with glass, to exclude the least dust or grit, which would at once interfere with its movements. At the end of the room facing the entrance may be seen the wires, which enter here from all parts of the city to the number of nearly two hundred, each with its little brass key with which it is thrown "into circuit." To the right of this frame of wires stands a large "annunciator," similar to that used in hotels; this is surmounted by a Morse magnet and a small gong. Below and in front of the annunciator is a printing machine, and on each side of this is a "dial machine" and pointer, similar to those used in the station houses. On the opposite side of the room a very beautiful piece of mechanism stands on a table, covered with glass and always ready for use. At the first glance, one would say it was a rather complicated musical box or a small barrel organ; for it has six drums with the stops and steel combs, and its operation is somewhat similar. To this instrument is entrusted the work of conveying an alarm to every engine house from the Battery to Harlem, which it does with "neatness and dispatch."

To illustrate, let us suppose that an alarm is struck on the gong. The number rung is 256; instantly the annunciator uncovers this number, and the printing machine writes it down three times and the gong repeats it twice. The wires are thrown at once into "circuit" by an operator, while another places a brass button bearing the same number on the spindle of the machine in the glass case, touches a spring, and off starts the automaton operator, striking 2—5—6 on every fire-gong in the city, making a pause of five seconds, and then repeating the 2—5—6, and yet again repeating the numbers after a similar pause. While this is going on, the same operator throws the wires to the bell towers into circuit, and the alarm is thrice sent to them; and, in less time than it takes to read the description, the bells are heard, and if the fire is near the office, the engines rattle by.

The next step is to make a record of what apparatus is at the fire, which is done by pulling out, from their receptacles in a neat frame, cards bearing the numbers of the engines and trucks which respond to a first alarm. This is scarcely done before 3—3—3 is rung on the gong. This is a private signal, sent from some box by a fireman, policeman, or perhaps one of the commissioners who has not heard the alarm distinctly and wants to know where the fire is. The number of the box whence the alarm came (2—5—6) is at once sent to the box designated by the annunciator, where it is rung on a little bell. Occasionally this inquiry comes from half a dozen boxes.

By this time, the bells in the office have ceased their twinkling, the automaton has given its alarm, the record of engines out is made, and the operators sit down to compare notes as to what bulidings are in the neighborhood of the box giving the alarm, and the probabilities of a large fire. But any apprehensions are allayed very soon by the signal 2—2—2—6, announcing that engine No. 6 has returned home from the scene of the fire, proving that it was either a trivial affair or a false alarm. No. 6 is returned to its place in the register showing that the district is no longer unprotected. The other engines announce their return in a similar way. In a few minutes after the last one has returned, a report of the property burned, the cause of the fire and the probable loss is received from the police station in the district, all of which is registered.

At some time during the night, or perhaps two or three times, the roll is called, to ascertain if the tower men are at their posts and awake. This is done by throwing all the tower wires into circuit, and giving the private signal, which is responded to by the watchers striking the numbers of their respective towers on the gong in the office. As an instance of how acute the sence of hearing becomes by constant training, it may be mentioned that an operator can almost certainly tell by the manner in which the numbers are struck whether the reply comes from the proper tower, or another watcher is answering. For instance, if tower No. 6 answers for itself, and then attempts to answer for No. 9, the difference in the manipulation for the longer signal will be detected by the operator at headquarters. In this case, or should no reply be received, a messenger is despatched to find out why the tower is without its occupant.

Of course, where instant action is required, it is necessary that the circuits be complete, the batteries all in working order, and the machinery without fault. To secure this, the aid of music is very ingeniously obtained. A number of magnetic coils are attached to the hammers of a harmonicon, and they with the plates of the instrument, form the opposite poles. To prove that everything is in proper order this harmonicon is thrown into connection with the other machinery, and if everything is right a complete octave from C to C is performed. Should anything be out of order one or more notes will be dropped, and the missing tone indicates where to look for the trouble.

Like all other telegraph lines, accidents will happen to the wires occasionally, and here another very ingenious contrivance is brought into use. Should there be any break in the line running up Third avenue, for instance, instead of sending a man to examine the wire from the central office to Harlem and back again, the circuit is made complete, a little instrument attached, and a current sent through the line, which travels until it meets the break, where, of course, it stops; and this point is indicated so exactly that the operator can tell almost the particular block in which the repairers must look for the trouble.—*New York Evening Post.*

INDIA-RUBBER INSULATED WIRE.

Any facts that may at times present themselves as bearing upon the duration of india-rubber or any other insulator must be a matter of some importance to telegraphy, and, being considered in that light, should be brought as much as possible before the telegraphic world, so that some advantage might be derived from the result of such facts.

Proof is every day obtainable of the lasting properties of gutta-percha insulated wire, especially in salt water, where it would appear to be imperishable. On land however, such favorable results have not been obtained, although it cannot be doubted but that gutta-percha, properly prepared, might last on land, or underground, as long as it could be desired. With india-rubber, however, we have not had such experience, principally for the reason that it has not been used much until latterly for the purposes of cables. The manner in which wires were insulated with this material was either with "pure" rubber or with "vulcanized" rubber. The former is the plan originally adopted, the latter the plan now in use. The "vulcanized" rubber-covered wire has been used for some long lengths of cable during the last five years, but this date is too recent for the purpose of the question of durability. The vulcanized rubber used has generally been that known as "Hooper's material."

However, if we go back to a period of just twenty years, we shall find that a four-wire cable, insulated with pure rubber, was manufactured, and any experience of the present state of that cable must be of interest. Therefore, having lately seen and inspected a specimen of that cable, we place before our readers the result of that inspection, and the history of the cable itself.

In the early part of 1852, Mr. C. West manufactured 2¾ miles of cables, consisting of four wires. Each wire was of solid copper, insulated by three lappings of strips of pure india-rubber of a narrow width; the four wires were laid up helically together round a core of yarn, and were then lapped over with one stout piece of yarn, well tarred; the whole was protected with a sheathing of plaited iron wires. During the summer and autumn of 1852, this cable (2¾ miles) remained coiled up in a yard, exposed to every vicissitude of the weather, the alternation of wet and dry, sun and shade. A cable could not be situated in a worse place. It was eventually submerged or buried in the early part of 1853, between Keyhaven, on the Hampshire coast, and Hurst Castle, and a piece was laid also across the Yarmouth River. The specimen examined was taken from the Hurst Castle section, where it had been buried in thick mud, covered by the sea from half flood to half ebb. The mud in this place is always moist, and but little change is effected in it by the flow of the water over it. The insulated wire may therefore be considered to have been placed in a very favorable situation.

The specimen examined was cut out near Hurst Castle, at the end of January, 1872; it had, therefore, exactly an age of twenty years.

The appearance of the cable was as follows:—The iron sheathing was oxydized, but offering still a very strong protection; on removing the sheathing, the yarn was found to be perfect, with a large quantity of tar remaining in it. The strength and goodness of the yarn was quite as excellent as it ever had been. The insulated wires had been considerably indented by the yarn, and discolored by the tar, but to all external appearance remained sound, these portions abutting against similar material, rubber against rubber, were, on being opened, in perfect preservation, and of a color apparently unchanged.

The insulation of the short lengths appeared good, for on being placed in water, and a current from 100 cells being passed into the wire, about one division was all that could be obtained on a delicate Thomson's reflecting galvanometer; on testing them, however, for retention of an electrical charge, it was found that their insulation was inferior, none of the wires were able to hold a charge for any lengthened period.

This result was not surprising, for, with the manufacture of such a cable at the date referred to, the insulation to be obtained, and the means of measuring it, were very different to what they are at the present time. Although the insulation of these wires at the present date is inferior, yet we may safely assume that it has not deteriorated since the date of manufacture.

A wire insulated in such a manner, with one strip of material placed over another, and so on, cannot be expected to give perfect insulation, for it would be impossible to make material so placed perfectly homogeneous. The means of testing at that date were necessarily, from the state of our limited knowledge and experience, very crude and imperfect, and doubtless, at that time, with a large amount of battery power and the best galvanometer then obtainable, the insulation was considered perfect.

On cutting and examining the wires, it was found that there was a fair adhesion between the several lappings, and the material of each lapping had the true color of freshly-cut india-rubber, retaining, at the same time, its elasticity. This may be considered as one of the principal tests of the material after a lapse of years. India-rubber as it gets old frequently dries and gets short, that is, loses all its elasticity, and may then be considered as good for little or nothing. In the present case, all the characteristics of good rubber were apparent, and its

Digitized by Google

state may be said to have remained unchanged during the long time it was lying in the Hampshire mud.

The long time this cable has lasted in such perfect preservation is doubtless due to the excellent material of which it was manufactured. At that time the largest quantity of rubber imported was that known as Para, the very best kind, which has remained at the head of the list ever since its introduction. With this pure material the wires of this old cable had been covered. Since that time rubber from various parts of the world, and of various qualities, has been largely imported, and the quality of the material now used is undoubtedly inferior to that of the pure Para. The want of success attending india-rubber covered wire on land lines may owe some portion of its failure to this reason.

The stripping of the final lapping of rubber showed the copper wire perfectly clean, and with a bloom on it apparently as if it had just been manufactured. Copper wire has generally been considered dangerous to be in contact with india-rubber, and all copper wire now manufactured is invariably tinned before being covered with rubber. We believe this to be a necessary precaution when vulcanized or other than pure rubber is used, but when the rubber is pure the copper appears to be harmless.

A good many faults in india-rubber covered wires have been ascribed to the action of the copper, for it has been generally found that in the old wire the copper was always oxydized whenever the rubber had failed, or had got soft and sticky. It would appear as if the saddle had been placed upon the wrong horse, and that the oxydation of the copper was due to the failure of the india-rubber, and not the reverse, and that therefore the extra cost of tinning copper wire before covering it with pure rubber has been a useless expense. It still goes on, although one would have imagined that the appearance of the self-same kind of faults, even with the use of tinned wire, would have shown its inutility.

To tin copper wire before covering it with pure rubber we cannot but consider as a useless expense, but it is doubtless necessary when impure or vulcanized rubber is used.

It must not be imagined that the whole of the cable we have been referring to has lasted so well, or remains in such perfect condition, as the piece which has been examined with such interesting results. During the long time the cable has been laid, many faults have appeared, and in many cases the india-rubber has become soft and sticky in its common manner; but it must be remembered that these faults have always shown themselves when the wire has been exposed in dry places, in places above ground, and at wind and water marks. In such places india-rubber has usually failed. The instance we have adduced is one in which its preservation is noticed when kept moist and deprived of light. This is, we believe, one of the best instances known of the preservation and duration of a wire insulated with india-rubber.—*Engineering.*

ELECTRO-MOTIVE FORCE OF DIFFERENT METALS.

(Abstract of a paper communicated by M. Edlund to the Academy of Sciences, Stockholm. Translated by C. W. Vincent).

In 1869, M. Edlund had demonstrated the following facts: Whenever an electric current traverses an electrometer in the direction of the current developed by that electrometer, the latter absorbs an amount of heat, proportionate to its electromotive force multiplied by the intensity of the current; and if the current is sent in the opposite direction, there is a quantity of heat evolved proportionate to the same product. With a current constant in intensity, the amounts of heat absorbed or disengaged are simply proportionate to the electro-motive forces.

If a voltaic current is sent through a wire made of two different metals, a change of temperature at the point of contact should be observed, because it is the seat of an electro-motive force; the temperature should be lowered if the current is in the same direction as that which corresponds with the electro-motive force, and it should be elevated in the opposite case.

Now experiment has shown that the temperature is raised and lowered at such a junction of different metals when a voltaic current passes through it, and that the change of temperature is proportional to the intensity of the current and to the electro-motive force.

It will be sufficient, then, to measure the amount of heat absorbed or evolved during the passage of the current, to obtain the valuation of the electro-motive forces which are manifested at the junction of two different metals.

This is the method which M. Edlund has employed in a series of experiments, in which he was assisted by M. Sundell, and of which the results have been submitted to the Academy of Stockholm.

The following numbers express the relative values of the electro-motive forces of the under-mentioned metals estimated in this way:—

Bismuth-copper, ...	141·3
Platinum-copper, ...	7·4
Copper-iron, ...	17·8

Zinc and silver approach so nearly to copper, that it cannot be distinguished if these metals should be placed before or after copper in the series of electro-motors.

The thermo-electric effects of the same metals were subsequently determined by direct experiments. Below is the result of some of these, calculated for a difference of temperature of 10 degress, and at a conductibility equal to 100. The second column of the table contains the electro-motive forces, as determined by the first method, and multiplied by a constant factor, so that the copper-iron combination has the same value as in the first column—

Combinations.	*Thermo-Electric Series.*	*Electro-Motive Series.*
Bismuth-copper, . . .	92·3 .	197 6
Platinnm-copper, . .	8·2 .	10·3
Zinc-copper, ...	0·9 .	0·8?
Silver-copper, . . .	0·6 .	0·0?
Copper-iron, ...	24·9 .	24·9

It is seen that the respective order of the metals is the same in the electro-motive, and in the thermo-electric series, although the contact forces are far from being proportionate in the two series. On the contrary, the series of electro-tensions, as it has been established by electroscope experiments, is very different. According to Seebeck, the metals are ranged in the following order, each one being electro-negative to that which follows it: silver, platinum, copper, iron, bismuth and zinc.

Other experiments have made this order slightly different, but with no greater approximation to the electro-motive series. It is probable that the electric tension does not depend solely on the contact of the metals, but also on the gas or liquids condensed at the surfaces of contact.

M. Edlund remarks, in addition, that, if the modifications which the electro-motive forces of contact should undergo, when the temperature is augmented, are calculated by the aid of the mechanical theory of heat, results are obtained which actual experiments do not confirm.

REGULATING THE TARIFF.

BUFFALO, Jan. 11th, 1872.

To the Editor of the Journal of the Telegraph:

Your correspondent on the subject of tariffs, in his letter to the JOURNAL of Jan'y 1st, stated that he has "A plan of tariff, &c.," which he will send, if desired, and in your remarks upon his letter, you gave a somewhat general invitation, saying that what was wanted is a plan which will promise success, not predictions of failure. I therefore take the liberty of considering myself one of the invited, and submit the enclosed plan in response to the "invite."

Without claiming that I have been the first to discover the plan, I will say, that I have given some thought to the subject, and have computed the distances, with a view to having the charges in proportion to the distance a message is to be transmitted, and have the system a just and liberal one, to the company, as well as to the public generally. My idea is to have each office the centre of a series of circles; first, a radius of 50 miles or less, for which a tariff rate of 25 and 1 is charged; second, circle of 100 miles or less, 35 and 2; third, 250 miles, 50 and 3; fourth, 500 miles or less, 75 and 5; fifth, 1000 miles, 100 and 6; sixth, 2000 miles, 300 and 20; seventh, 3000 miles, (or the distance from ocean to ocean,) 600 and 40. These distances, as well as the rates charged, can be increased or lessened, as the tariff bureau may see fit. Each office is to have a common map of the United States, in place of a tariff book. The circles are of course, stamped on the map, "for instance, for N. Y. office, New York will be the centre; for Chicago, Chicago will be the centre, and so on." My intention with the enclosed map, is to merely show the principle on which the plan is supposed to work.

This idea, or a similar one, may have been thought of and discarded as impracticable by the tariffites, in which case I shall have had "my trouble for my pains."

Yours,

TARIFF.

Note.—This is precisely the plan of our correspondent, * * * and is the old Russian plan, which on general principles of simplicity and justice, is, with a country bearing in all its parts like conditions, the simplest and best ever adopted. The state tariff, if it could be freed from exceptions, is, we believe, the best for America.

ELECTRIC PROBE FOR WOUNDS.

In the last general assembly of the Scientific Association of France, M. Trouvé exhibited and described his probe for the search and extraction of foreign bodies remaining in wounds. Surgeons have at all times been occupied with the discovery of a simple and practical means, capable of revealing to them to a certainty, the presence of any foreign body in the tissues. Since Garibaldi's wound, two plans have been proposed, the one frictional and the other electrical. That by friction (Dr. Nélaton's plan) was preferred to the employment of electricity, proprosed by M. Favre, of Marseilles, which was the subject of a communication to the Academy of Sciences. The style of probe which Dr. Nélaton uses to discover the presence of a ball has at its extremity a small "rugous" or wrinkled porcelain ball, which becomes blackened in contact with a leaden bullet. This plan is, without doubt, ingeneous, and in this special case of great utility; but the services which it can render are very limited. In fact the body, the presence of which it is sought to verify, must be of lead, and the wound should not be closed very straight, nor even very curved. This verification becomes even impossible when, as frequently happens, the bullet is encysted or covered with a portion of muscle or cartilage, or even with a fragment of the clothing of the wounded person.

The apparatus of M. Trouvé consists of three distinct parts: a battery, a probe, and an indicator (*révélateur*). In principle, it is founded on the difference in conductibility between metals and other bodies. The battery is formed of a zinc and carbon element, enclosed in a case of hardened India rubber hermetically sealed, the exciting liquid being bisulphide of mercury. The probe is a pipe, flexible or rigid, constructed so that the preliminary probing may be effected, and then the stylets of the indicating apparatus may be introduced. The indicator contains in its interior a very small electro-magnet with a vibrator and two small rods of steel, very sharp and insulated from each other; and as soon as these points, which are in connection with the battery touch any metallic substance, the vibrator begins to move.

With this apparatus, it is possible to distinguish the different metals from one another. If the metal is lead, the trembler vibrates regularly; if, however, it is iron or copper, the trembler has a jerky movement.

RAILROAD ROAD WIRES.

To the Editor of the Journal of the Telegraph:

Since my article entitled "Railroad Wires, their Uses and their Abuses," appeared in your issue of December 15th, I unfortunately had not seen a number of the JOURNAL until a few days ago, and was not aware it had called out other expressions of opinion on the subject of train orders. In looking over the Journals for February, I see quite an interest has been awakened, and am glad to notice that some of the writers have clear views on the subject. "Western Dispatcher" in the JOURNAL of February 15th, explains very intelligibly, the system of which I spoke, and shows its advantages over other systems aside from its economy in the use of the line. His points are strong ones, and should be read carefully by all Train Dispatchers. "Another Observer" in JOURNAL, No. 102, seems to think it might do occasionally to send an order to both trains at one time, but that it would not answer in every case. This is only a mistaken idea—there never was an order given but that properly worded could not go to both trains in exactly the same form. The custom of making train orders, read to "Conductor and Engineer," and having both their signatures repeated, and then correct it thus: "To Conductor and Engineer, O. K" —is another slight abuse of circuit. It is right that the engineman of a train should have a copy of the order, and be held personally responsible for any accident that may happen from his misunderstanding of it; but it isn't at all necessary that the order should be addressed to him and come back with his signature—it is only a waste of time. Let there be a rule on the time card compelling enginemen to have a copy of the order in their possession, and making the violation of this rule a cause for dismissal. There is much more that might be said on the subject of train orders; that there should be a uniform system adopted by our Railroads for moving trains by telegraph, and also, that there should be a uniform code of signals agreed upon would seem to need no argument. The chances for accidents would be lessened, insuring greater personal safety to travelers, and to the corporations a decrease in losses of rolling stock, &c.

OBSERVER.

MOBERLY, March, 18th, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—Some time ago, mention was made in the JOURNAL of an "Automatic" telegraph, or device for transmitting and registering telegrams automatically. I have a good deal of curiosity to know whether it is a resurection of the old devices of Morse, Bain and others, or if it does really contain anything new. Will you be good enough to enlighten me on the subject, also, if the thing still lives, or has "gone where the woodbine, &c."

Yours, respectfully,

D. H. FITCH.

It is the same cat with a new collar. The question of existence is in debate. There seems just breath enough to prevent a funeral.

RED MESSAGES.

ORRVILLE, O., March 27, 1872.

To the Editor of the Journal of the Telegraph:

I am pleased to see that "S," of Cleveland, has let out on the present mode adopted by most offices in transmitting half rate messages.

When the order for receiving "red" messages was promulgated, I interpreted it as being the idea of the Company to create a system by which the lines would be brought into greater use during the night, *after* the business of the day has been cleared up, but at present the setting of the sun seems to be the signal for rushing in the "red" messages, and in many cases, in contention with, and to the delay of, the unfinished business of the day. In this way the bulk of the half rate business is crowded in during the early hours of the evening, largely on the time of the day men, leaving the lines unoccupied later in the night.

Why not fix upon a certain hour, say ten o'clock, before which time no "red" business is to be transmitted? Offices where no night operator is employed might be permitted to commence on half rate business at eight o'clock, but not make it general to all until nine or ten P. M.

Yours, &c.,

EQUALIZER.

LIGHTNING PROTECTORS.

CLEVES, OHIO, March 27, 1872.

To the Editor of the Journal of the Telegraph:

Referring to the article on lightning rods in the last number of the JOURNAL, I give you my experience with them:

I have for several years had charge of repairs of the I. C. & L. R. R. wires. In 1866 three different sections of our line were particularly troubled with lightning. Hardly a storm passed but one or more poles would be shattered. While my poles were being struck so frequently, I was struck, (not with lightning,) but with this idea of rods from top of pole to the earth. I did not see how it could affect the main circuit and thought it might save my poles, where my interest lay. Accordingly, without the knowledge of my Superintendent, I put on the lightning rods in the troubled sections. They are there to this day and have been a complete success.

Last Summer we had trouble in the same way near Lafayette, an application of lightning rods there had the desired effect. I also put the rods on the first three poles each side of the Superintendent's office at his residence, and he was not troubled during our worst storms.

From this I believe it would be well at river crossings to put rods on the first eight or ten poles next to the cables.

RICHARD C. RUSSELL.

OPERATORS AND THE TARIFF.

To the Editor of the Journal of the Telegraph:

Every number of the JOURNAL of late has been of much practical interest. When operators begin to show their lack of knowledge, and ask for light, for instruction, we may justly hope that a better day is dawning among us.

In the issue for April 1st "Old Man," in referring to wages paid, and the competency of operators, touches a subject which has been too much neglected. Given competent operators on all our lines and the vast amount of check errors, which now seem unavoidable, would be a thing unknown. At present, however, at least three out of every five are not qualified in respect to a knowledge of the English language; and very few understand the rules as printed. As to counting words, here is a specimen:—"I start for St. Paul to-night, arrive there to-morrow, from thence by Rock Island, Council Bluffs and Kansas City to St. Louis"—checked 24, Paid—each name and compound word being counted as two words. In another case, in answer to a message asking how much sugar the person had on hand, the reply was: "I have one hogshead," the sapient operator insisted on making "hogshead" two words.

I differ with all who have gone before on the matter of the present tariff system. It is an admirable arrangement; the great trouble being that operators will not pay attention to entering up the names of new offices as fast as received. The only trouble with the tariff book is, its being so deficient in space for the entering of new names; and especially so under particular letters. In the Supplement this should have been attended to, but was not. Should another book be issued, this point should be carefully arranged. I have had to make an extra book for some letters.

Not far from me is an office which has not entered up a new office during the last six months. Some offices pay no attention to the rule in regard to offices near them within 25, 50 and 75 miles, but go by squares in all cases. I do not like the newly devised system by States; believe it would not be understood but by few, and therefore cause much confusion.

TELEGRAPHER.

ASSUMPTION, ILL., March 27th, '72.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—I notice lately a communication in JOURNAL from some very liberal Manager, advising the W. U. Telegraph Co. to revise and re-issue the Tariff book quarterly; that he would be willing to pay, etc., rather than be continually scratching out and entering changes as they occur. Now I verily believe the W. U. Co. able to furnish tariff books to her office managers free of charge. My tariff book is very much mutilated, as I presume most others are, and would be pleased to be presented with a new one complete to date. If the Company contemplate issuing a new book I would make the following suggestions: That it leave no space for entering names of new offices, but that there be a space about $\frac{5}{8}$ inch at the left of each page for entering in small figures (red Ink) the number of JOURNAL on same line with any office, whose Tariff, Name, Co. or P. O. address has been changed since issuing of previous JOURNAL, and that the JOURNAL leave space at left of new office column for same purpose, and that it be an imperative duty of all managers to preserve in perfect order each file of the JOURNAL. Also that each office be furnished one of Emerson's Self-Binders for the purpose, making a perfect book of them, that the JOURNAL, instead of issuing the change of name of an office as at present, note it in alphabetical list: example, "318 Arcola, Ill., heretofore Okaw, Ill."

Am inclined to the opinion if the above suggestions were carried out there would be no need of a new issue of Tarif book for next ten years, even if the Government should act so wisely as to keep her fingers out of the Telegraph business. Permit me to say also that I think it the duty of every knight of the quill, every lover of political economy, every one who desires our present enormous taxes reduced instead of increased, who are opposed to Government putting her procrastinating heel upon private enterprise, diving headlong into an enterprise which will be detrimental to *tens of thousands*, and beneficial to comparatively but few, should write, say, and do every thing honorable in opposition to the Postal Telegraph Movement.

W. W.

NEW YORK, April 4, 1872.

To the Editor of the Journal of the Telegraph.

Sir:—What is the "invention which bids fair to double the capacity of existing wires," vaguely hinted at in your editorial of this week? Or is it a secret?

Yours,

AN OUTSIDER:

ANSWER:—We referred to the plans of Mr. Stearns in so arranging machinery and currents as to enable a single wire to do the work of two. By a peculiar arrangement, which we are not at liberty yet fully to describe, messages can be sent by the same wire, both ways, at the same time, without interfering with each other. It is a noteworthy achievement.

MORE TRAIN ORDERS.

EASTERN DIVISION PITTSBURGH, FT. WAYNE AND CHICAGO RAILWAY.
April 11, 1872.

To the Editor of the Journal of the Telegraph :

I have read the various learned opinions in the controversy between the advocates of their respective systems of train orders with considerable interest, and believe that a little experience meeting is beneficial amongst telegraphers as well as others.

In speaking my little piece, I desire to differ *from* the "Old Man" whose fifteen years experience has taught him that in an order for trains No. 1 and 2 to meet at A, that the conductor of No. 2 can fall back on his dignity, or schedule rather, and refuse to proceed until he has received a *positive* order giving him the right of road against No. 1. Methinks I hear an audible smile amongst the old stagers. When the dispatcher says to two trains they should meet at A, can anything be more positive that he intends them to meet at that point, and that each has an equal right to proceed to A, and for neither to pass that point until the other has arrived, regardless of anything the schedule may say? If not, why have the despatcher at all if a plain order like that is counteracted by the schedule?

Probably no road in the Union makes better use of the telegraph in the moving of delayed trains than the Pittsburgh, Ft. Wayne and Chicago, as the trains are numerous, and it requires close figuring to get a delayed train through without detaining others. The system adopted I think would serve as model for all.

When the dispatcher wishes to give orders to trains, he calls up both the offices wanted, and sends the same to each at one writing. All orders are copied on manifold paper by which as many as are required are made at one writing, and all exactly alike. These orders are then signed by the conductors and repeated back. With the dispatchers O. K. the exact time from the regulator is given by which conductors and operators can note any variation of their time-pieces. All orders are numbered by the dispatcher, thus in repeating or referring to at any time the order meant is readily designated by the number. Two copies of each order are given to each conductor (one for the engineer.) As the freight trains frequently run in sections of two, four or more, the dispatcher always notifies the operators how many copies to make. For convenience, the manifold paper is prepared in packages and marked 3, 5, 7, &c., as the case may be, so that the operator can, on the instant, be ready to copy as many as the dispatcher may request.

The form of the orders is generally of a simple nature, as follows: "To conductor No. 1, A; conductor No. 2, C; Nos. 1 and 2 will meet and pass at B," or No. 11 has until 3.45 P. M. to run to B ahead of No. 1," or No. 2 will run to B regardless No. 1," or "No. 5 can use 10 minutes on time of No. 7 to run from A. to B." This system, with the manifold paper, requires less time and is safer than any other I have ever came across. With the manifold paper properly prepared, an operator can copy four or five different orders, and can be ready to repeat them back as fast as the dispatcher wishes to send them. Collisions and kindred unpleasant things are ruled out on this system. SCAT.

ANOTHER VOICE ON TRAIN ORDERS.

TRENTON, Mo., April 11th, 1872.

To the Editor of the Journal of the Telegraph :

A great deal has been said on the subject of train orders through the JOURNAL. "Old Man" offers some very good suggestions in your last issue in regard to employing competent operators on railroads, which, of course, can never be had at salaries paid by a great many roads at the present time; but his ideas of train dispatching seem to me to be rather old. Of course no train dispatcher, who understands his business, will give a train an order to proceed against another train having the right of track, without first giving the order to the latter, or placing an order ahead of it to hold it for orders. In the order he quotes: To conductors and engineers, Nos. 1 and 2. "Trains Nos. 1 and 2 will meet at A." I have always regarded an order of this kind a positive order for both trains to run to the designated point, regardless of each other—irrespective of time and schedule rights. By substituting the following: "To conductors and engineers, Nos. 1 and 2—No 2 runs to A, regardless of No. 1." This, of course, would give No. 1, the train having right of track, the stipulated schedule time to make A.

On the subject of duplicating train orders, it is my opinion that at the present stage of railroading it cannot be worked with success. Where, as it is most generally the case, a large number of operators are also station agents and have other duties to attend in and out of the office, it would consume more time in the end than the old system of sending each order separately. It would be, perhaps, seldom both offices could be made to respond just at the same time. However, I consider the plan a good one; but, until reliable operators are placed at every station, with no additional duties to perform, it cannot be worked to advantage. With a good schedule of rules, and train men who understand them thoroughly, I think the shortest form of train orders, which will embrace what is required and be understood by all, sent to each train concerned separately, is the safest and the best. Yours very truly,

A VOICE IN THE WILDERNESS.

PACKING MESSAGES.

The business of "packing messages" has grown to great and inconvenient proportions in London, and was discussed at the telegraph conference recently held at Rome, but no method was devised whereby it might be stopped. "Message packers" are persons who defraud telegraph companies of part of their charges in various ways, but generally by reversing a message and making it appear as a cypher. For instance, the charge for sending a message to India is ninety shillings for twenty words, including the address, and a firm in London agrees to forward messages for ten shillings a word, and as it has its agents in Calcutta who understand its cypher several messages may be sent by the use of twenty words; if ten messages are thus sent ten pounds are paid for them to the firm, which receives therefor ten pounds from its customers, and of course pockets five and a half pounds. Another method of "packing" is to reverse a sentence, send it as one word, and—if the words be short, in which case only this plan is feasible—something will be made by the operator, since in ordinary messages five letters are allowed for each word. It may possibly be true that similar means of sending messages cheaply are adopted in this country, but as yet no firm has been heard from which makes a business of such action.

THE "Wonders of Electricity" is an interesting volume, and our correspondent, P. J. Huder, Algiers, La., can find it in any good book store in New Orleans. It is published by Scribner, New York.

MR. K. S. V. RANDOLPH has determined to open a school of Telegraphy in New York, where every branch of the business in all its details will be taught.

ROCKPORT, IND., April 18th, 1872.

To the Editor of the Journal of the Telegraph :

DEAR SIR,—A lady came in my office and sent a message. In about an hour after she had gone her husband came in and sent a message to same person and with same contents the former had sent. Was it my duty to have told him that that message had been sent, without his asking me? By answering the above in your next issue you will greatly oblige

OPERATOR.

Answer.—Your duty was to take, in silence, both messages. A receiver is presumed to know nothing of the contents of any message.

EATON, O., April 10th, 1872.

To the Editor of the Journal of the Telegraph :

DEAR SIR,—Please give opinion as to rule 24, which says, "Messages must be sent as written." Does it include misspelled words? I have noticed quite a difference of opinion among operators in regard to the matter of spelling; for example, I had a message sent to my office, a few days since, with the word "sugar" spelled with two "g's." Receiving operator refused to take it unless I would spell it correctly. Yesterday I received (from a large city office) a message containing the word "write" spelled without the "w"—*rite*. Would it not be well, when we can, to call the attention of the writer to any improper spelling? But where we haven't an opportunity of seeing the sender of a message, is it not equally well to send the message as written? We can't tell but what sender may convey quite a different meaning to receiver by misspelling some of his words. Has a receiving operator any right to object to a message because improperly spelled?

Yours truly,

S. S. DIX, Manager.

Answer.—The subject above is one which appeals to the intelligence of a manager. Follow copy is the only safe rule. No other directions can be given. Corrections can only and should always be made in the presence of the sending party.

To the Editor of the Journal of the Telegraph :

Here is a nice question on which I should like your opinion :—

A customer of ours doing a large business to Baltimore, frequently leaves out the place of destination on his telegrams, and in his hurry rushes off; but we in the office, being so familiar with the firm to whom message is directed, and knowing the writer also, forward it on. Now in case of any trouble for non-delivery or delay, or other matters of like nature in which the Company is threatened with a law suit, is his ommission of the place of destination not in our favor? Yours, &c.,

JERSEY.

ANSWER:—The sending it at all, would seem to destroy the whole argument our correspondent suggests. An unaddressed telegram is no telegram at all. The court might so hold it, and the carelessness of the one be allowed to offset that of the other. We do not know.

Houston & Great Northern.

This railroad, which has reached the Trinity, will be extended eight miles north of that stream to a station called Trinity as soon as the bridge over the Trinity is completed, which will be within two or three weeks, the road-bed being ready and the iron on hand. The branch to Huntsville will be completed about the same time.

Elizabethtown & Paducah.

A correspondent inform us that work on this road is progressing most satisfactorily.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JAMES D. REID, Editor,
Executive Rooms, Western Union Tel. Co.,
145 Broadway, New York.

NEW YORK, MAY 1, 1872.

GOOD BYE.

On this bright May morning, on which the whole blooming earth is smiling to the sun, we stand on the door-step of our old home to say adieu. Let no one blame us if there is a tremble on the lip while we utter it. Twenty-seven years have not passed without a love springing up for a grand business which we aided to nurse. We drew up the first code of rules for the management of telegraph lines. We opened, or aided in opening, the first commercial telegraph office. We were the first elected superintendent of a commercial company. We were the first to use iron wire in America. A good many things now in use we might claim a hand in bearing. We entered into telegraphic life with a whole heart, and gave it all our life. Such bonds cannot be broken without emotion. It would be harder but for the ripening. Yet we cannot shut the door on which our hand fondly lingers, or look into the faces of so many of you whom we have loved and labored with so long without feeling the bitterness of a parting hour.

In reference to our own now ended work we have little to say. Our sphere latterly therein has, perhaps, been deemed a little one, yet we have done therein what we could. We have never pretended the possession of extraordinary knowledge, or any special facility of composition, and so we have, at least, broken no promise and have excited no false expectations. We have endeavored to do the duty assigned to us with a simple desire to make a small service fruitful of good, and to infuse into whatever we wrote an element of kindness which might beget itself in others. This we deemed a worthy ambition. Some have assured us of success in this design, and it gives us pleasure to know that we have passed through so many years without knowingly hurting the feelings of the humblest of all who have served with us in the widening ranks of this great service.

In retiring from our duties as Editor of the JOURNAL OF THE TELEGRAPH, we have great pleasure in saying that its direction hereafter will be in hands fully as competent, and with an experience perhaps more practical than our own.

Mr. Fred. J. Grace, well known to the fraternity, has been appointed to the Editorship of the JOURNAL, and with the issue of May 15th, his work in that connection will begin. We think we can promise all a healthy, dignified, practical management which will sensibly increase the usefulness and attractiveness of the JOURNAL.

The JOURNAL with its present volume seems just entering a career of genuine usefulness. The discussion, for example, about train orders has brought out a correspondence which has already attracted the attention of railroad managers, and will lead to investigations of the details and possibilities of telegraphic railroad direction. Already a convention is asked to consult on this very subject. Now let the JOURNAL be so used as that it shall bear the best thoughts of our best and most practical men, as well as of humbler men who yet look with intelligent eyes upon the responsibilities they have assumed. The new Editor, Mr. Grace, has that practical talent which will enable him to set all these suggestions in their best light, and render all such discussions full of promise of positive good. So now we have only space to say to you all, and we say it very kindly, very tenderly, and indeed, very sadly, farewell.

JAMES D. REID.

As an evidence of the value of Mr. Stearn's machinery for the transmission of messages both ways over the same wire at the same time, we give the following from the manager of the New York office.

On April 10th, between New York and Boston, the following operators were placed on duty, in connection with a single number nine wire to be worked with Stearn's machinery.

Messrs. Catlin and Dwight, New York.

Messrs. Beardsley and Stewart, Boston.

Catlin sent to Beardsley in one hour, from New York to Boston, messages	72
Stewart, Boston, sent to Dwight, New York, in same time	64
Total by one wire in one hour	136

The messages were not selected, but were the regular business of the office, many of the messages being long ones, ranging from ninety-one words down. No office messages were included; all were regular numbered messages. The actual time consumed was fifty-eight minutes, two minutes having been lost by interruption.

Here is a vast advantage gained. No automatic plan approaches it in positive value. It is the most marked advance yet made in telegraphic service, for though it does not quicken the process of transmission, it practically does so by doubling the capacity of every wire.

THE Morse memorial meetings throughout the country have been of the most intensely interesting and imposing character. To all of these we would gladly have thrown open our columns had it been possible. Yet there is so great similarity in expression, in sympathy, in the ascription of well-defined honor to the dear dead so lately by our side, that we feel that already enough has been said. Imposing proceedings have been held at Boston, Washington, Philadelphia, Rochester, N. Y., Frederick, Md., Memphis, Tenn., Pensacola, Fla., and hundreds of other places in which the most distinguished citizens heartily and feelingly joined. Never in man's history was a life more complete. Even the enmity of the few who sought to sully his name is hushed and silent by the side of the flower-strewn tomb where the good man sleeps.

WOMEN telegraphers in Baden do not seem to meet public expectation. Carefully selected young women were, a few days since, placed in charge of the offices under that Government, and it was not long before unaccountable delays began to be observed in the transmission of messages. It has just been discovered that the operators have made it their regular practice to defer any petty dispatches about matters of State or business until they had finished sending each other glowing accounts of parties and dresses and delicious bits of gossip. The result is that the powers that be have ruthlessly dismissed the fair offenders and re-instated the old employes.

K. S. V. RANDOLPH, a practical operator of many years' experience, is making arrangements for opening an Evening Telegraphic Institute in this city.

Persons of either sex desiring to acquire a knowledge of Telegraphing, as applied to Commercial or Railroad service, together with the system of Bookkeeping pertaining thereto, can ascertain all particulars by addressing Box 3393, New York.

WE have received a lithographic sketch of the new building of the Montreal Telegraph Co., in Toronto, and nothing could better illustrate the prosperity and vigor, and public spiritedness of the management of that company. Whatever Hugh Allen touches seems to turn to gold, and no man is more fortune in the men who serve under him. Mr. Dakers the Secretary at Montreal and on whom a large amount of executive work depends is a gentleman whose personal worth and earnest devotedness to his work, is as well known and for as many years as the system itself. How he enters into the enjoyments of those who serve under him is seen in his presidency of the Montreal Snow Shoe Club, and it must be a rare sight to see the now venerable secretary and the boys "sledding" down the Montreal hill sides in the moonlight winter nights, with a whoop and a yell such as would frighten out of his propriety a New York executive. Glorious old James Dakers, may you slide down your last hill as merrily and as glad of heart. Not less marked as a rare executive officer is our friend Mr. H. P. Dwight the Superintendent. By rare practical talent, energy and appreciation of the public wants, he has made the Canadian telegraph system unique in telegraphic management, and as popular as it is liberal and successful. The new building, large, roomy and elegant in all its parts, is a sufficient commentary on the management which made it possible to build it, and the magnitude of the business which made it essential.

IN answer to an enquiry we reply that there is no life of Professor Morse extant. This was to have been our Summer's work, but we now hesitate to undertake it, although it was Mr. Morse's desire that if done, we might do it. We have two very large photographs of Prof. Morse on hand, cost $5 each, by Bogardus. Three fine engravings of him will be sent, post paid on receipt of twenty-five cents.

MR. S. ROBERTSON, formerly General Superintendent of the North-western Telegraph Co., has been elected Vice President of that Company, and Mr. Chas. H. Haskins has been elected General Superintendent. These are most excellent appointments conferred on worthy men.

MANY communications come to us about vacations and the duties of employer and employed in reference thereto. We wish we had the power to order a general suspension of labor for all the leafy month of May or June, or its later sister, July, so that every operator, messenger, and manager could off to the woods or wheresoever they might list. But these are matters of government we pretend not to understand, except on the general assumption of the benefit to all of one brief breathing time in the circuit of the year. We leave, as we must, the possibility of granting furloughs to those whose business it is, and to the circumstances under which they may be granted or denied. To one or two points we call attention:

To grant a furlough, implies that the labor of an office can be performed by less than the usual help, or that the business is so slack as to permit of the absence of part of the usual force. Now, no establishment managed on correct business principles ever undertakes deliberately to provide for such a necessity. And the executive of a company has no right to do so. Their business is to provide sufficient force for the public service, at fairly remunerative salaries, and no more. In the telegraph offices where one man is appointed to a single wire, it is easy to see that even a diminished business does not give, as it might in other pursuits, the opportunity of one man doing the work of two, although it is sometimes done. A reduced or enlarged business on a wire, each still alike calls for the care and attendance of the man who serves it. If he goes, and one man serves two wires, the danger is, that it will be at the hazard of the detention of business. Two calls at the same time must result in one having to wait for the other. It is this which makes companies fearful of the absence of their men. It is a most difficult point to solve, how, without an actual increase of the usual necessary force, furloughs can be given at all, and how far a company is justified in thus increasing its force.

A pleasant correspondent remarks: "granted that this policy puts money into the company's treasury, has it not something of the appearance of selfishness? What else can it be called when the health and strength of those who make the money for a corporation are sacrificed for the sake of a few thousand dollars increased receipts yearly?" Now, all business is selfish and nothing else. The lines are built to make money, and the operator labors for the same end. It may be very sordid, but we live in a very sordid world, and the interest and duty of a company is to make it pay, and yet preserve all those moral obligations due from man to his fellow, which no position or business can ignore. If vacations will secure health and improved capacity of service from operators, it is the interest of companies to grant every facility for securing the greatest bodily vigor, and will do so, if from no higher motive, from selfishness alone. We have no doubt that the time will come, that with the company's successful arrangement of its capital, its thorough hold on Society as an acknowledged permanent integral part of the chief national industrial agencies, these questions of health will form a more conspicuous part of its policy. It has commenced providing for its dead It will not long forget the living.

THE firm of F. L. Pope & Co., manufacturers of the Nonpariel machinery, already so widely known and in use, have removed to 194 Fulton Street, N. Y., where they are not only more accessible but have more ample room to transact their increasing business.

FROM St Louis we have the following circular, to which we give publicity with much pleasure. By a kind of instinct Railroad companies are very generally employing telegraph experts to the service of train dispatching. The telegraph is a great necessity now in the arrangements of all Railroad train management, and the interest in the service is shown in the numerous letters we have published on that subject. We hope the convention will be held, and be fruitful of good. It has our heartiest approval, and the tender of any aid we can render it.

TO ALL TRAIN DISPATCHERS.

St. Louis & Iron Mountain Railroad Co.,
Office Supt Telegraph and Train Dispatcher,
St. Louis, April 6, 1872.

DEAR SIR.—The question of a general system of "Train Dispatching" for the Railroads of the United States is becoming a most important one, and I consider it to the advantage of all Railroad Companies, and those interested in their management, to co-operate in my efforts to call together a convention of Chief Train Dispatchers from all parts of the United States and Canada, for the general interchange of ideas, the establishment of the best and most uniform system of train dispatching, and, if deemed desirable, to form an Association, to hold stated meetings, and the appointment of Committees to report upon such business as may come before the Convention.

I would therefore respectfully suggest the propriety of your consideration of this matter, and would be pleased to have your views upon same as soon as possible, in order to make the necessary arrangements for assembling the Convention at such place as may be decided upon. Very Respectfully,

W. W. WELLS,
Supt. Telegraph and Train Dispatcher.

WE have to record the death of Mr. Richard Waterman, of Lafayette, Indiana, night operator and train dispatcher of the T. W. & W. R. R. Co., at that place, the result of an attack of typhoid fever in the Summer of 1871. He died April 8th of consumption, in his 24th year. Mr. Waterman was a man of exemplary christian character, and was the main support of his parents. He was a member of the Telegraphers Insurance Association.

OSCAR JENNINGS operator Western Union Telegraph Co. at Chicago, died in that city April 24th.

IN reply to H. we have to say that if the propriety of opening an office on Sunday for any period is granted, it is not possible to exercise any discrimination in the messages received, except to exclude those of obvious obscenity, or profane. Yet we would be glad to see Sabbath labor limited to the utmost. On the general question we cannot now with propriety enter.

H. W. B. does not perceive that to give Reds all the advantages of full paid messages would be to give a preference to Reds not at all contemplated. It would draw unduly from the day service and for which the Company is not yet prepared.

SENATOR RAMSEY has again introduced the subject of the Postal Telegraph in the U. S. Senate. No action is expected thereon during the session.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
May 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since April 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

OFFICES CLOSED.

Red River, N. Mex.

GENERAL INFORMATION.

Offices which have recently received new rates to Jersey City, N. J., will charge the same for Marion and Hudson City, N. J., and 15 cents more than New York rate for Hunters Point, L. I.

Hereafter the "Tariff for other lines" from Great Falls, N. H., to Wakefield, N. H., will be 25 and 2.

Offices having "Special Sheet A.," will hereafter check Newport, Ky., same as "special rate" to Cincinnati, O., and Canastota, N. Y., same as "special rate" to Rome, N. Y.

Attention of special offices north and west of Washington, D. C., is called to special rate to Savannah, Ga. The rate was made one dollar more than special rate to Washington, D. C., October 11th, 1871. Square rates then in force were not to be increased.

ATLANTIC CABLE BUSINESS.

On and after May 1, 1872, the ten word minimum on business between all W. Union offices and points in Great Britain and Ireland, will be abolished.

The tariff will thereafter be computed by multiplying the number of words, whether more or less than ten, by one tenth of the present rate for ten words (or by the present rate for additional words.)

This change does not apply on business destined for points bayond England.

WILLIAM ORTON, Pres't,

IN reply to F. H. I. we answer. The earth is an infinitely large conductor, and to our mind, practically acts as a return wire, except that, because of its great volume, it is without appreciable tension. There is a scientific way of stating this, but it amounts practically to this although seemingly denying it. The "flow" of the current as it is called, is not now admitted to exist. Atoms of matter change their relation to each other, or, as it is called, become polarized.

BALTIMORE, MD., March, 23d, 1872.

To the Editor of the Journal of the Telegraph:

A thought occurred to me of a plan by which the membership of the Telegraphers Mutual Life Insurance Association might be increased if the rules of the Association were such as to admit. I allude to it in my own imperfect way—hoping a discussion of the subject may follow with some beneficial results.

It is this: If our brother and sister operators who do not think it necessary at present to insure, would grant other members the privilege to effect an insurance on their lives, I do not doubt there are many could be found willing to carry a number of policies in view of receiving in the event of death the amount due on the party insured. Or as a speculation to hold until the person whose life is insured may make up his or her mind to purchase the policy and thus become a member in fact.

Instances sometimes occur where a brother or sister, after protracted illness, may not be in condition financially to keep assessments paid up. For the benefit of such, would it not be well to make some provisions by which policies held by them could be prevented from dropping off by default. Since they cannot be reinstated under the present rules of the Association, unless by paying up arrears. I think there should be an effort made to aid in some way a continuation of membership. Will the Association secure me even the amount required to pay—arrearages for those in default if I bring them again within the fold. Respectfully,

"TEMPERANCE."

There is no objection to any one paying up dues owing by another, but money at death can be paid to designated heirs only. It is not a proper field for speculation.

INSURANCE IN THE WEST.

I did not expect when I sent you the letter which you published in last JOURNAL, to make myself a general Western medium for the "Telegraphers Life," but it would seem that such is the accepted fact. I am daily receiving applications for blanks from those desiring membership in the Association, from all parts of the West; have heard from Iowa, Missouri, Michigan and Kentucky, with Ohio included. I am glad to see a feeling manifested to strengthen and increase our Association, and will cheerfully do my part. Those sending applications to me, will have to furnish additional stamps for return of certificate, unless they wish them sent direct from New York. It seems from the tone of the letters, that our Western operators don't know who the proper New York officers are, and seeing my name at the end of your letters published, apply to me for instructions. I will keep you informed as to telegraphic news, &c., hereabouts.

Yours truly, H.

DELAYED PAYMENTS.

ST. JAMES, MO., March 28th, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR,—I wish to call the attention of members of the Telegraphers' Mutual to a resolution, passed long since by the executive committee, setting apart delayed payments on assessments for expense account. Under the articles of association the heirs of deceased members are entitled to one dollar for each member in the association at the time of the death. This resolution diverts money that belongs lawfully to dependents of deceased members to other uses than that intended. Money, too, that is often badly needed by those to whom it rightfully belongs. Expenses of the association must be met; but a special tax ought to be assessed for this purpose, and not by taking from the heirs of deceased members.

I, for one, would willingly pay a reasonable extra assessment for this purpose, and have no doubt but that the majority of the association would; and, thereby, relieve the orphans of the expenses incident to the workings of our order.

Please submit the spirit I have attempted to express above to the association, and in so doing greatly oblige Yours, J. B. MORGAN.

The subject is one fairly open to criticism, yet there should be some date at which an account should close, and the settlement should be complete when made. Practically, it has had little operation, as complete settlement has been delayed until all but a few straggling remittances have been received. What goes to expense account is from those who, by the rules, have been excluded, and who are re-admitted on application and payment of back dues.

To the Editor of the Journal of the Telegraph:

A young lady operator copied a message the other day in which occurred the question, "Where is Mother French?" Her copy read, "Where is monkey wrench!"

Another operator, a brilliant youth, received a railroad message in which the word *signal* occurred three times. Just as he had finished copying the message he left for supper, being relieved by another operator. His relief took up the message from the table and puzzled over it a long time, but could not understand it, as it was written in three paragraphs, with "nal" under each, and the signature at the bottom.

Upon the return of the "gay and festive cuss" who received the message, he said it was "three messages in one," and asked, "Who is *Nal?*"

He thinks of applying for a position as train dispatcher!

This reminds me of a similar bull which was made at the time of the laying of the first Atlantic cable. A copy of an official dispatch, signed by Cyrus W. Field, was sent to the operator at ——, who copied the signature thusly:—

Sig——

"*Ned Cyrus W. Field,*"

and sent it with that signature to the chairman of a large public meeting, which was being held at the time, who read it to the audience. I never knew till then that Mr. Field's first name was *Ned!*

AUGUSTUS.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—I would like to give the readers of the JOURNAL an opportunity for a "hearty laugh." A gentleman came to my office to send a message, and after writing it, waited as people often do at small offices, to see it sent. I called office, and operator came to key and said, "Busy, wait a minute," so I leaned back in chair to wait, when the gentlemen said, "Have you sent it?" I said "no, they say they are busy, to wait a minute," whereupon he said, looking surprised, "Why, I didn't hear them," and then added, brightening up as if he had thought of the reason, "but I'm *a little deaf in one ear!*" I think I managed to keep a straight face till he left but it was hard work, and those to whom I have related it seemed to enjoy it so much, I thought the readers of the JOURNAL might.

Respectfully, M.

ONE should never impart anything to a woman under the seal of secresy. This old experience was lately renewed by a telegraph operator at the railroad station of Friesack, near Berlin.

He received, namely, a telegram from a merchant in Berlin, who had married some four months previously, the daughter of the Mayor of Friesack, addressed to an employer of the railroad company, which read, "Send hear immediately your daughter as wet nurse. A little boy has arrived with us." This piquant news the operator told to his wife "under the seal of secresy," and she under the same promise, hastened to impart it while fresh to her friends. After the lapse of an hour the whole of Friesack was aware of the news. The operator was condemned to three months imprisonment, and various persons were fined five dollars each, for slander. The parties have appealed and will obtain a new trial.

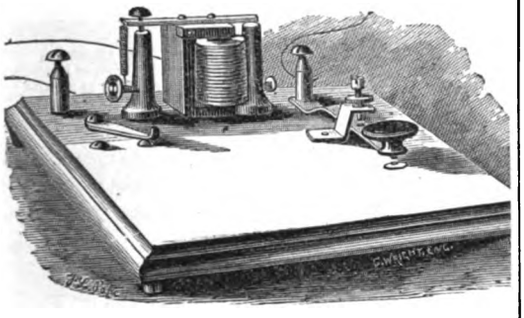
A DISGUSTED TEXAS PLUG.

CORSICANA, Texas, Feb. 23.

To the Editor of the Journal of the Telegraph:

I am a young man desirous of completing my course, over half accomplished, as an agitator of the Electric Fluid. I have written to various operators and superintendants, exhausting time, patience and money to that end. Finally, succeeded in getting into Corsicana, Texas, office, where, the operators employed, seem to treat me with contempt; the office is somewhat scant of furniture, and I was compelled to purchase a box to sit on. Every morning when I came on hand to practice or listen at the batteries, I find my box nailed to the wall, about ten feet from the tables. The operators give me no show at all; seem to be too busy to reply to a civil question, else they make out so. Is there no redress, and are all operators of same disposition toward beginners? I appeal to you for advice, and hope you will favor me with an answer, through your valuable paper. Do you think I can get these two operators discharged, and how shall I go about it? To give you a sample the way I am treated, I asked one of them if he *honestly* thought I ever would learn; his answer was couched in terms insulting in the extreme, "said: He thought the agricultural interests of the country was going to rack and ruin, just by the absence of my sort from the field."



Where can I complete my course, and at what price? Respectfully refer you to Rev. W. G. Veal, M. E. Church South, Presiding Elder, for character and respectability.

Yours, much disheartened,

D. B. ADAMS.

THE NONPAREIL TELEGRAPH APPARATUS.

(Patent applied for.)

This apparatus supplies a want which has long been felt, viz.: that of a SIMPLE and CHEAP

MORSE TELEGRAPHIC INSTRUMENT,

with all the necessary Batteries and other appurtenances in a CONVENIENT and COMPACT form.

By means of a switch, which is now placed on each instrument, they can be worked as desired, either as the open or the ordinary continuous, or closed circuits.

It is intended especially for the use of

STUDENTS, AMATEURS, AND OPERATORS,

but will be found to be equally well adapted for use on

PRIVATE TELEGRAPH LINES,

or Short Lines of any description, which are not over three or four miles in length.

A NEW FORM OF BATTERY

is employed, which is compact, efficient, and economical, and especially adapted to the purpose for which it was designed. Each instrument will be accompanied by a

BATTERY, CHEMICALS, INSULATED WIRE for connections, together with an

ILLUSTRATED BOOK OF INSTRUCTIONS,

which in itself forms a complete elementary treatise upon the ART OF TELEGRAPHY.

PRICES:

Single Instrument, complete, with Batteries, etc.....$8 00
Two Instruments, " " " " 15 00

Sent by Express on receipt of price.

Remittances may be made by Post Office Order, Registered Letter, or Draft payable to our order. Persons ordering Instruments will please write plainly, giving Post Office, County, and State, with instructions for shipment. Address,

F. L. POPE & CO.,
P. O. Box 6010. 194 Fulton Street, New York.

THE NONPAREIL TELEGRAPH APPARATUS may be procured through the leading dealers in Telegraph Supplies throughout the country.

☞ SEND FOR A CIRCULAR. ☜

16,000 MILES

OF

"JOHNSON'S" WIRE

USED BY THE

TELEGRAPHS OF THE UNITED STATES

DURING THE YEAR 1871.

This is sufficient refutation of all the intimations thrown out by the Manufacturers and Importers of other Wires, reflecting upon the acknowledged superiority of the Wire manufactured by

Messrs. RICHARD JOHNSON & NEPHEW,

MANCHESTER, ENGLAND.

Their Works are the Largest in the World.

The great advantage which they possess over other manufacturers is their patent process of drawing Wire in great lengths (averaging 1,200 feet).

All Telegraphers know that, in nine cases out of ten, breaks in Wire occur at joints, hence the less joints the fewer breaks.

Messrs. RICHARD JOHNSON & NEPHEW furnish three-fourths of all the Telegraph Wire used by the

ENGLISH GOVERNMENT.

This Wire is necessarily subject to the tests, etc., imposed by the English Post-office Department.

A large stock always on hand and for sale at the lowest market prices—both free and in bond.

AMERICAN FIRE ALARM

AND

POLICE TELEGRAPH.

GAMEWELL & CO., PROPRIETORS,

NO. 104 CENTRE STREET, NEW YORK.

J. W. STOVER,
General Agent and Superintendent.

L. B. FIRMAN, Chicago, Ill.,
General Agent for the West and North West.

J. R. DOWELL, Richmond, Va.,
Special Agent for Virginia and North Carolina.

J. A. BRENNER, Augusta, Ga.,
Special Agent for Georgia and South Carolina.

L. M. MONROE, New Canaan, Conn.,
Special Agent for New England.

This system of Fire Alarm and Police Telegraph, with a Central office, or upon the

AUTOMATIC PLAN,

is now in operation in the following cities, to which reference is made for evidence of its great SUPERIORITY, VALUE and UNIFORM reliability:

Albany, .N Y.,	New Orleans, La.,
Alleghany, Pa.,	New Haven, Conn.,
Boston, Mass.,	Newark, N. J.,
Buffalo, N. Y.,	Omaha, Neb.,
Baltimore, Md.,	Philadelphia, Pa.,
Chicago, Ill.,	Pittsburg, Pa.,
Cincinnati, Ohio,	Portland, Me.,
Columbus, Ohio,	Peoria, Ill.,
Cambridge, Mass.,	Providence, R. I.,
Charlestown, Mass.,	Quebec, L. C.,
Covington, Ky.,	Rochester, N. Y.,
Detroit, Mich.,	Richmond, Va.,
Dayton, Ohio,	Indianapolis, Ind.,
Elizabeth, N. J.,	St. Louis, Mo.,
Fall River, Mass.,	St. John, N. B.,
Fitchburg, Mass.,	Springfield, Mass.,
Hartford, Conn.,	San Francisco, Cal.,
Jersey City, N. J.,	Savannah, Ga.,
Louisville, Ky.,	Syracuse, N. Y.,
Lawrence, Mass.,	Troy, N. Y.,
Mobile, Ala.,	Toledo, Ohio,
Montreal, Canada,	Toronto, Canada,
Milwaukee, Wis.,	Washington, D, C.,
New York City,	Worcester, Mass.,
Lynn, Mass.,	New Bedford, Mass.,
Lowell, Mass.,	Bridgeport, Conn.

The distinctive features of these systems of

FIRE ALARM AND POLICE TELEGRAPHS.

ARE,

First—The AUTOMATIC SIGNAL BOXES, the simple electro-mechanism of which enables any one—even a child—to give an *instantaneous, general,* and *definite* alarm of fire.

Second—The AUTOMATIC REPEATER, through which the apparatus may be distributed in a combination of circuits, and the entire system successfully worked without the constant personal attention of either operators or watchmen.

Third—The ELECTRO-MECHANICAL BELL STRIKERS, adapted to produce the full tone of the largest church or tower bells.

Fourth—The ELECTRO-MECHANICAL GONG STRIKER, for hose and engine houses, by means of which the location of the fire is instantaneously communicated to the members of each fire company.

These features combined form the

ONLY PERFECT, COMPLETE, AND RELIABLE SYSTEM

OF

FIRE ALARM TELEGRAPH IN THE WORLD.

Messrs. GAMEWELL & CO. are the owners of the original *FARMER AND CHANNING PATENTS,* one of the most important of which has just been extended for seven years. During the past seventeen years they have spared no expense or effort to secure improvements, and the systems are now covered by

MORE THAN TWENTY PATENTS.

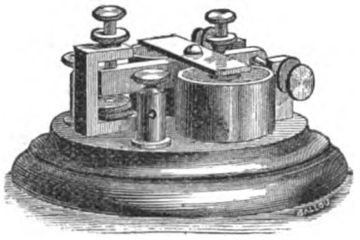
The introduction and operation of the

AUTOMATIC SYSTEM

involves so little expense, compared to the benefit which it confers, that even small communities can profitably adopt and maintain it.

The co-operation of TELEGRAPHERS in securing its introduction into their localities is cordially invited, and their efforts will be duly appreciated and compensated.

Any information desired in regard to the above system will be cheerfully and promptly furnished upon application at the office.



A pamphlet setting forth more fully its advantages and superiority, has been printed, and will be supplied to Municipal Authorities and others interested in Fire Alarm and Police Telegraphy upon application as above.

MECHANICAL TELEGRAPH INSTRUMENT

PATENTED MAY 31st, 1870.

For Students, Colleges, &c. No battery required. An ordinary key and sounder is placed upon a proper base. The sounder is moved by a lever under the base, connected with the key, making a perfect instrument for those wishing to learn the Art of Telegraphy. An expert could not tell, without examining it, that the instrument was not worked by a battery.

It should be introduced into every school and family where there are those who wish to learn the Art.

Hundreds of persons throughout the country desire to become expert Telegraphists, and are constantly seeking permission to practice in the various telegraph offices.

This instrument is an outgrowth of this pressing demand. The Inventor is himself a practical operator, now in active service. Operators and others wishing to teach or learn the Art, will be delighted with this instrument.

It can be placed anywhere, as it does not occupy a space more than six inches square.

Its cost is but $7, and there is no expense whatever to keep it constantly in working order.

We will send a copy of SMITH'S MANUAL, free of charge, with each instrument, to individuals or clubs. The instructions in this Manual are particularly adapted to those who wish to learn by sound.

Special and liberal terms to manufacturers.

Remittances can be made by certified draft on New York, Cleveland, or Pittsburgh, money by express, charges paid, post office order, or registered letter at our risk.

Parties ordering instruments, from points except well-known cities, will please give the name of county and State.

Price, $7. Silver Plated, Extra Finish, $10.

Address, D. W. PUTT & CO., Wellsville, O.

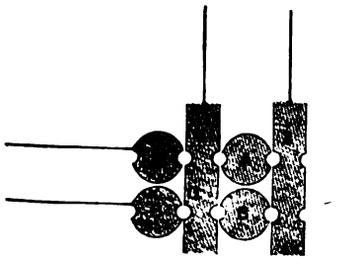
JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 12. NEW YORK, MAY 15, 1872. WHOLE NO. 109.



THE PEG SWITCH.

In our last issue we gave an illustration of a portion of one section of the switch in use in the New York office. The switch, itself, is known as the "peg," so called from the metallic plug, or peg, used in forming or changing circuit connections.

As the peg switch has been adopted by the Western Union Telegraph Company as a standard, it is, of course, desirable that all engaged in the business should become familiar with the principle of its construction. To this end we will describe it in its simplest form, devoid of spring-jacks and other auxilliaries which enter so largely into the composition of the New York switch. The peg switch is composed of a series of vertical metallic bars, or strips, to which are attached the line wires, and of a number of metallic buttons, or discs, placed horizontally. To these latter are connected the instrument wires.

The accompanying diagram shows the connections of the peg switch as adapted to the requirements of a way office. It is so simple, and yet so perfect, that only a very brief explanation of the reference marks upon the cut will be necessary to a full understanding.

1 represents a vertical metallic bar, or strip, upon the switch, to which is connected a wire running into an office, and 2 represents the same wire going

out. A and A′ and B and B′ are metallic buttons, to which are connected the instrument wires. All the buttons upon the same horizontal line are connected together at the back of the switch.

As shown in the cut, the circuit is "open." To close it, with instrument in circuit, it would be necessary only to insert two metal plugs, or pegs; one at the orifice at B′ and 2, and one at A and 1. The course of the current would then be as follows: From the line at 1 through the peg connection at A to instrument; through instrument to B and B′; through the peg connection there to the line at 2, and so out to the main line. Should it be desired to connect the line through, without instrument in circuit, the insertion of pegs in the orifices of either A′ or B′ would effect the desired result.

The same form of switch, with a modification of connections, would answer for a terminal office.

For this, let it be understood that a wire, leading from a battery, one pole of which is grounded, is taken directly to one side of the instrument; through the instrument it goes to A; from A, if a peg be inserted in its orifice, it goes to 1 and to the main line.

If, instead of placing the peg at A and 1, it be placed at A′ and 2, the instrument would be connected to line 2.

It will be seen that in the terminal form, but one line wire is necessary to be on the switch, and but one wire to the instrument to form a circuit, while in the way form two of each are required.

POSTAL TELEGRAPH SCHEME.

We give herewith the letter of Mr. G. B. Prescott, Electrician of the Western Union Telegraph Company, to the Hon. James B. Beck, of Kentucky, upon which was based the masterly argument delivered by him in the House of Representatives at Washington, January 27, 1872, against the latest effort of, or more properly speaking, perhaps, the latest scheme of certain designing parties, who are endeavoring to obtain possession of the various telegraph properties in the United States, by coercion through Congress. The letter, in itself, is so complete, as to fact and statistics, that it will be read with general interest.

There is certain valuable statistical information in tabular form, appended to the document, but which, however, is so well covered by Mr. Prescott, in his letter, as to render its reproduction, here, unnecessary:

ELECTRICIAN'S OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, January 16, 1872.

DEAR SIR: Mr. Orton has handed me your favor of December 28, with directions to furnish you with such information in my possession as you require. I therefore inclose, herewith, statements showing the number of miles of line and wire, and number of instruments in operation in all the countries of Europe, altogether, with the number of telegraph offices, population, number of messages sent, and the receipts and expenses of the service. The statistics for the continental countries of Europe are for the year ending December 31, 1869, the latest year for which complete returns have been received; while those for Great Britain and Ireland are for the fourteen months ending March, 31, 1871.

In Europe the telegraph system embraces 175,490 miles of line, 475,007 miles of wire, and 15,503 offices. The number of messages transmitted was 33,141,386, the gross receipts for the transmission of which were $15,146,551.20 in American gold currency, and the expenditures $19,558,016.76, being an excess of expenditures over receipts of $4,411,465.56. The tolls for the transmission of messages are not the same for any two countries in Europe, nor are they uniform for all classes of messages in any one country. Telegraphic correspondence in Europe is divided into two general classes, called internal and international messages. The internal messages are those which are received, transmitted and delivered in the same country. The international messages are those which are received in one country and transmitted into another. As a general rule, a low rate of charges is adopted for the transmission of internal messages, while a higher tariff is imposed upon international messages. The average rate for internal messages throughout Europe is thirty-six and six-tenths cents, and for international messages $1.01. In the official report of the telegraph system of the United Kingdom of Great Britain and Ireland, the internal and international messages are not stated separately, only the total number, including both classes, being given, but the average tolls upon the whole service amounted to forty-two and a half cents per message. The average expense per message for the performance of the telegraph service in America and Europe was about the same, although it is well known that skilled labor is much more expensive in this country than in Europe. It would appear from the results that although the telegraphists in Europe get less pay for their labor than similar employes receive in America, a larger number are employed there than here to perform a given amount of work. As it is, however, to Great Britain that the Postmaster-General invites especial attention as having given to the telegraph a practical test of the public system as compared with that under private control, I will point out the leading features of its operation in that country.

On the 5th of February, 1870, the telegraphs were transferred to the British Government. At the date of the purchase the various telegraph companies of the United Kingdom possessed sixteen thousand miles of line and eighty-five thousand miles of wire. For this property the British Government have already paid, according to the official report of Mr. F. J. Scudamore, the second secretary of the Post-Office Department, £7,500,000 sterling, or $36,450,000 in American gold currency.

This sum of money, however, does not comprise the entire sum which the British Government must pay to acquire the control of all the telegraphs in the United Kingdom.

Arrangements have been made with sixteen railway companies for the purchase of their telegraph interests, in which the compensation consists partly of capital sums and partly of annual payments, and with six other railway companies, in which the compensation consists wholly of annual payments; and there yet remain, according to Mr. Scudamore's report, made to the House of Commons on the 12th of July, 1871, forty-four railway companies in various parts of the United Kingdom with whom the Post-Office Department has not yet come to arrangements as to the amount of compensation to be paid to them for the purchase of their telegraph interests.

From the above-mentioned official report the amount of telegraph revenue from the commencement of governmental control, on the 1st of February, 1870, to the 31st of March, 1871, was £798,580, or $3,865,127.20, and the expenditures for the same period were £1,397,389, or $6,763,362.76, being an excess of expenditures over receipts of $2,898,235.56. The disbursements are classified by Mr. Scudamore under the heads of capital expenditure and working expenses; the working expenses being stated at £470,495, or $2,277,195.80, and the capital expenditure at £926,894, or $4,486,166.96.

We ought not to be surprised that Mr. Scudamore, through whose efforts mainly the British Government was induced to purchase the telegraph lines, should make every endeavor to prove that the administration of the telegraphs by him was pecuniarily successful. I do not feel disposed to criticise his report in an unfriendly spirit, but I cannot refrain from remarking that the enormous excess of the capital expenditure over working expenses naturally leads to the suspicion that many charges have been carried to the former account which properly belong to the latter, and an examination of the detailed statement of the working expenses confirms the justice of this suspicion. Under capital expenditure is placed, not only the cost of extensions, amounting, as well as I can make out, to £178,933, but all manner of outlay upon the plant, such as the very important item of maintenance and repair, for which our company expends about a million dollars a year, £177,094 for engineering, salaries, wages, traveling and other expenses, a considerable portion of which should certainly be charged to current expenditure. Among the working expenses there are no charges for poles, wire, insulators, instruments, battery material, office repairs and furniture, and many other items which constitute a large annual charge to private telegraph companies; and if those expenditures which are improperly carried in Mr. Scudamore's report to capital expenditure were placed where they properly belong, I have no doubt but that the working expenses would be found to largely exceed the revenue.

The English telegraph system, when it was purchased by the Government, was the oldest, most extensive and, probably, the

Digitized by Google

st managed in Europe. And there is no reason, if properly managed under Government control, why it should not have continued to give satisfaction; but since its acquisition by the Government, the complaint of bad service has been very general. The difficulties have been ascribed to the large increase in the number of messages offered for transmission, and to the inadequate preparations to accommodate the immense increase in the traffic which immediately followed the large reduction of rates, but according to the report of Mr. Scudamore, the average cost of inland messages is twenty-six cents, against an average cost prior to the transfer of thirty-eight cents, showing a reduction in price of less than one-third upon this class of messages, while there was no reduction whatever upon international messages. According to the same authority the total number of messages forwarded in the three quarters ending 31st December, 1870, was 7,563,015, which is a less number than was transmitted by the Western Union Telegraph Company alone during the same period; so that the difficulties complained of were not properly chargeable to the excessive amount of traffic performed.

The expenditure in a single year of $2,898,235 in excess of the receipts, the opening of 1,350 new offices, and the erection of over 45,000 miles of additional wire, ought to have vastly improved the capacity and value of the British system. The work of reorganization and extension was intrusted to the officers of the companies which were bought out, and the position of engineer-in-chief of the post office telegraphs was given to Mr. Culley, the former electrician of the Electric and International Telegraph Company, with a salary largely exceeding that paid by our Government to the Cabinet ministers. I see no reason why the British post office telegraph system should not equal any other in the world, nor why, at the rates charged, it should not be self-sustaining; but this does not tend to prove that the union of the telegraph and postal systems in this country would be a wise or profitable measure.

The British post office has long enjoyed an enviable reputation. It promptly and satisfactorily carries and delivers letters at one penny each throughout the United Kingdom, and makes a net profit of over five million dollars per annum; while our post office charges three cents for carrying a letter without delivery, except in the larger cities, and manages the business at an annual loss of over four million dollars. Of course it does not follow that because there is a large annual deficit in our post office that there would necessarily be one proportionally as great in the telegraph if managed by the same department, but when the success of the British telegraph is presented to us as a conclusive demonstration of the utility of the postal telegraph for this country, it seems proper to consider whether the management of our postal system is sufficiently analogous to that of the English to warrant the deduction that whatever is successfully undertaken by the British post office can be equally as well performed by our own.

When the project of a postal telegraph was first started, Mr. Gratz Brown proposed to establish a uniform tariff of three cents per message of sixty words. Mr. E. B. Washburne followed with a proposition to make the tariff fifteen cents for ten words, exclusive of address and signature; while Mr. C. C. Washburn at first proposed a uniform rate of twenty cents for thirty words, but subsequently changed it to twenty-five cents for twenty-five words, charging for address and signature. Mr. Creswell does not name the rate which he thinks should be established in the event of the acquisition of the telegraph by the Government: but perhaps the rate is indicated in the following query, extracted from his recent report: "Who, that desires to convey or acquire any information, would hesitate between sending a telegram from New York to California in seven minutes for twenty cents and sending a letter in seven days for three cents?"

If such a rate for the transmission of messages between the Atlantic and Pacific States by the postal telegraph shall ever be practically inaugurated, I have no doubt the letters carried by mail between these points will be materially reduced; but I apprehend that the annual deficit in the Post Office Department will not thereby be sensibly diminished.

The Postmaster General admits that a large sum of money will be required for the purchase of the present telegraph lines, but considers that delay will only add to the amount of purchase-money required. The Post-Office Department, he says, is now prepared to undertake the organization and management of the telegraph, in connection with its other duties, and can aid materially in raising the money needed for the purchase through post office savings banks, if Congress will authorize their establishment. To prove the feasibility of this latter scheme he refers to the history of the British post office savings banks, "which, after ten years operations, have in $75,145,690, a much larger sum than will be required for the purchase and thorough repair of all the telegraph lines in the United States." But is it probable that Mr. Creswell can purchase the lines for the sum named, even admitting that his postal savings bank scheme is successful. The President of the Western Union Telegraph Company, which operates fifty-six thousand miles of line, one hundred and twenty-five thousand miles of wire, forty-six hundred offices, and transmits over ten million messages annually, and whose revenue is more than double that of the British post office telegraphs, has recently publicly announced that his company is inflexibly opposed to any interference of the Government with its business or the acquisition of its property. Our company has been quietly pursuing for the past six years the same object which the British Government has been accomplishing since it acquired the control of the lines, namely: the unification and enlargement of the telegraph system, accompanied with an important reduction in the rates for transmitting messages. With the exception of half a dozen comparatively small connecting and competing lines, this company controls the whole telegraphic system of the United States, its lines covering a territory embracing twenty-five degrees of latitude and fifty-five degrees of longitude. Within the past five years the telegraphic facilities in the United States have been increased by the construction of thirty thousand miles of line, the erection of seventy thousand miles of wire, and the opening of over three thousand telegraph stations, and the annual increase is constantly augmenting. During the same period the average rate of tolls has been decreased fifty per cent. Is it probable that the telegraph would have made greater progress under Government control during the same period?

The various telegraph companies transacting business in competition with the Western Union Company own about ten thousand miles of line, and are represented by an aggregate capital of over sixteen million dollars. It is not probable that these companies have earned enough to cover their current expenses, and it is well known that some of them have already incurred debts for a greater amount than their property is worth. There is every reason, therefore, why these concerns should look with favor upon a Government purchase, and I presume that their managers are actively at work to bring about such a result.

It is a fact worthy of mention that although the land lines in Europe are almost exclusively owned by the various Governments through which they extend, the submarine lines, over which all the important communications with Asia, Africa, Australia and America are transmitted, are owned by private companies. The length of the submarine lines now in operation is thirty-six thousand three hundred and two miles, for the construction of which upward of sixty million dollars of private capital has been expended, of which at least one-quarter has been devoted to the construction of cable lines in Europe for the express purpose of avoiding the Government land lines, where important communications were subjected to such serious errors and delays as to render them comparatively useless. One of the most marked instances of this kind was the construction of a submarine line from Falmouth, England, to Malta, a distance of twenty-eight hundred and sixty-four miles, in order to avoid using the Government lines in France. These private submarine telegraph lines can scarcely be overrated in their relation to the commerce of the world. They extend beneath the Atlantic and German oceans, the Baltic, North, Mediterranean, Arabian, China, Japan and Red seas, the Persian Gulf, the Bay of Biscay, the Straits of Gibraltar and Malacca, and the Gulfs of Mexico and St. Lawrence, thus uniting the whole civilized world in one continuous chain of telegraphic lines. Messages from the United States destined for India, China, Japan, or Australia, would not pass over a rod of governmental telegraph line.

Yours respectfully, GEORGE B. PRESCOTT.

Hon. JAMES B. BECK.

PROGRESS OF INVENTION.

No one is able to fix a limit to human ingenuity. Ever since the organization of civil society new plans have been continually multiplying to lessen labor and protect man against man. Labor-saving machines, therefore, have increased so vastly it would be quite impossible to catalogue them. Although it would seem difficult to contrive more complicated locks than are now patronized by banking institutions for the safety of their treasures, there are regiments of rogues at large whose skill in opening them is absolutely superior to that of those who contrived them. If hundreds incarcerated in prison for the crime of burglary were honestly exercising their extraordinary ingenuity in a legitimate way, monuments of mechanical ingenuity, infinitely surpassing any yet seen, would unquestionably be called into existence.

TURKISH TELEGRAPHY.

According to a recent writer, "Telegraphs were introduced in Aleppo, Syria, a few years ago by the Government, and now reach about all the places of any importance; but let not any one suppose that telegraph means the same in Turkey that it does in America. The motto of everybody in this country is "*Yavash, yavash*" (slowly, slowly), and even electricity is handled by these phlegmatic Turks in accordance with their time-honored customs. Electricity is altogether too fast for the average followers of the prophet; but, as it pays no heed to "*yavash, yavash*," after it is started, the Turkish operator delays the message as long as possible at one end, and the Turkish carrier at the other end waits till a quanity of telegrams have accumulated, and then devotes half a day to delivering the arrivals for the week. Let me mention a couple of cases that occurred under my own observation a few days ago. One gentleman telegraphed to Aleppo from Antioch, distant about one hundred miles by telegraph route, and got his answer in just forty-eight hours, though his agent in Aleppo answered immediately."

WEATHER SIGNALS.—The government of New South Wales, following the lead of Europe and the United States, has introduced the system of telegraphing the anticipations of the weather, and has established certain stations on the coast for indicating the nature of any expected storm by means of signal masts. These signal masts support two yards, crossing each other at right angles in the direction of the cardinal points of the compass. A violent squall is to be represented by a conspicuous diamond-shaped signal; a heavy sea by a drum; a gale with clear weather is indicated by a diamond-shaped signal over a drum; and one with thick weather and rain, with the same signal under a drum. The direction in which the wind is blowing is indicated by the particular yard-arm between which and the mast-head the geometrical signal is suspended. Gales that are general over a large portion of the coast are indicated without the mast-head flags, by the geometrical figures.

A GALVANIC PENHOLDER.—To those familiar with patent records, there is no lack of inventions notable, not for their usefulness, but their oddity, and for the misconception of cause and effect shown in devising them. Occasionally one of these may be mentioned as an illustrative example. For instance, a gentleman with a genius as unique as inventive, lately incurred the expense of an English patent for a device for securing steadiness to the hand of a penman by a novel application of galvanism. He makes the penholder of an outer tube of copper and an inner one of zinc; the former being perforated, so that, when grasped by the fingers and thumb in the act of writing, a portion of the inner tube will be brought in contact therewith. The moisture of the skin is expected to induce a gentle voltaic action between the two metals, and this, acting upon the hand, is designed to steady the shaky nerves, and thereby secure comparatively faultless samples of chirography. Ridiculous as this seems, there should be little surprise if, in some cases, the desired result were actually obtained. Imagination has a mighty influence upon the control which people have of muscles, nerves, and tendons, and the man who can persuade himself that his hand is steadied by the mysterious influence from a twopenny galvanic penholder may, perhaps, improve his handwriting as the result of credulity, if not of science.

REMOVAL AND IMPROVEMENTS IN THE DETROIT OFFICE.

The office of the Western Union Telegraph in Detroit, Mich., has been transferred to Buhl's new block, on the southeast corner of Griswold and Congress streets, and a very handsome and convenient location it is, too. The business office for the reception and delivery of messages is in the basement, to which there are two public entrances, one on Griswold and the other on Congress street. Passing through either of these doors, the visitor finds himself in a nicely lighted and well furnished office, across which is constructed a black walnut counter with glass fronts. The space behind the counter is occupied by the officials, clerks, etc., of the line, and an entrance leads from Congress street to this department. It is provided with all the modern conveniences, including a large vault with one of the Detroit Company's safes. By means of a "Blacksmith's Blowers" messages are propelled through a tube to the operating room with astonishing celerity. The apparatus is simply a rotary air pump. A message is placed in a leather box in the air-tight tube, and three revolutions of the crank, by which the pump is operated, is sufficient to force it in a jiffy to the opening at the top, and there it drops into a wire basket. The box is then emptied and returned to the business office below through another tube. The invention is exceedingly convenient, and is far superior to the old "dummy." The telegraph company occupy the entire top story of the building for various purposes, but their operating room is located in the corner. Running into this department are forty-eight wires, and here thirty-two instruments are kept busily clicking the news from all parts of the world. The room is large, is lighted on two sides, and is supplied with every possible convenience. The instruments and apparatus generally are all of the new and improved patterns, and the institution is supplied with everything that is desirable for the transmission and reception of telegrams from every quarter of the globe that is traversed by telegraph wires. The new headquarters are creditable to the enterprise of the company, as well as to the business community, whose employment of the telegraph makes these extensions of facilities imperative.

THE FIRST IDEA OF THE TELEGRAPHIC DIAL.—In a work written by Father John Laurechon, a Jesuit, printed in 1624, at Pont-à-Mousson, under the title of "Récréation Mathématique composée de plusieurs problèmes plaisants et facétieux," there is to be found a curious passage, well deserving to be quoted:—"It is stated, that by means of a magnet, or any stone of the kind of load-stones, absent persons could communicate with each other; for example, Claudius being in Paris, and John in Rome, if each had a needle rubbed with some stone having the power, as one needle should move in Paris the other could move correspondingly at Rome; Claudius and John could have similar alphabets, and having arranged to communicate at a fixed time every day, when the needle had run three times and a-half round the dial, this would be the signal that Claudius wished to speak to John and to no other. And supposing that Claudius wants to tell John that 'the King is at Paris,' he would move the needle to the letters *t*, *h*, *e*, and so on. The needle of John agreeing with that of Claudius would, of course, move and stop at the same letters, and by such means they could easily understand and correspond with each other. This is a fine invention, but I do not believe there is in the world a loadstone having such a power, and besides it would not be expedient, as then treason would be too frequent and too secret." Father Laurechon used to write under the assumed name of H. Van Etten. Annexed to the passage quoted, there is a diagram of a dial, with the 24 letters, having the needle fixed at the letter A. A similar allusion is to be found in the Dialogue of Galileo.

SAFETY MATCHES.—Casualties are continually occurring from fires caused by ignition from the still burning ends of lighted matches thrown carelessly aside; and it may be of interest to learn that a mode of preparation has lately been devised by which such a result may be entirely prevented. The principle of the new match consists in impregnating the wood of which it is made with a chemical solution which prevents the carbon from remaining a fiery mass for a single instant, as in the case of ordinary matches, so that as soon as it is blown out it may be thrown with perfect safety upon inflammable or explosive substances. The manufacture is said to be no more expensive than of those now in use.

PROBABLE TEMPERATURE OF THE SURFACE OF THE SUN.—An animated discussion has recently been going on in the French Academy of Sciences respecting the probable temperature of the surface of the sun. It was commenced by Pere Secchi, who has experimented on the effect of the solar rays in heating a thermometer. Assuming that the radiation of heat from all bodies is proportional to their temperature above the absolute zero, he finds that the temperature of the sun must be at least *ten million degrees* in order that it may radiate the amount of heat we actually receive from it. The French physicists all take strong ground against this conclusion, and cite the researches of Pouillet, who, by nearly the same method, found that the required temperature was only 1500 degrees, approximately that of the hottest furnaces.

The difference of the results arises partly from the different laws of radiation adopted. Pouillet adopted the law of Dulong and Petit, founded on actual experiments, which showed that the quantity of heat radiated by a body increases in a geometrical ratio, while its temperature rises in arithmetical progression. The French argue that this law, being based on actual experiment, is to be preferred, and Vicaire uses it to derive the solar temperature from the experiments of Secchi, and finds the result to be only 1398 degrees, less than a thousandth part that of Secchi. M. Vicaire's communication was followed by remarks from four members of the Academy, who all coincided with his views. M. Fizeau called attention to his own experiments, which showed that the light of the sun was only twice or three times as bright as the electric light, as proving that the solar temperature could not be many times higher than that which we are able to produce artificially, and which does not exceed three thousand degrees centigrade.

PROGRESS IN MECHANICAL SCIENCE.—The progress in mechanical science is shown by the statement of Dr. Lardner that 480 tons of coal, with an engine and hoisting-machine, would have raised every stone of the Great Pyramid to position. It should be remembered that the Great Pyramid weighs 12,760,000,000 tons, and, according to Herodotus, it took the labor of 100,000 men twenty years to build it.

ELECTRICITY AND NERVE FORCE.—Mr. J. St. Clair Gray, of Glasgow University, Scotland, has recently observed the mutual action of sulphur and phosphorus in alkaline solutions, and the idea that such action might be the source of an electric current occurred to him. Accordingly he prepared a cell containing caustic potash in solution, and placed in it sticks of phosphorus and sulphur; and he found, half an hour afterward, that the sulphur remained unaffected, while the phosphorus had settled in an oily mass to the bottom of the alkaline fluid. Phosphoretted hydrogen, spontaneously inflammable, was given off during the first six days; but after this time the gas became somewhat sulphuretted, and no ignition took place. The test by Sir W. Thomson's electrometer, made by a qualified assistant of that eminent philosopher, showed the electromotive force to be 162, while a Daniell, acting under similar conditions, exhibited 120 only. A remarkable feature of this battery was that the fluid phosphorus on being removed and washed, still retained its liquid shape. Sticks of solid phosphorus were introduced, and they not only did not help the liquor to solidify, but speedily became deliquescent themselves.

Mr. Gray's object was to obtain data to support a theory on the origin of nerve force, he being convinced that the power of the nerves has an electric element in it. He was induced to make the experiment described above by the well known facts that phosphorus is largely present in the brain and sulphur in the liver, and that an alkaline fluid is in constant circulation between them. He has tested this theory by experiments on a rabbit, and considers that he is justified in assuming that his explanation of the existence of galvanic action between the brain and liver is correct and well founded.

TRAVELING STONES.—Many of our readers have doubtless heard of the famous traveling stones of Australia. Similar curiosities have recently been found in Nevada, which are described as almost perfectly round, the majority of them as large as a walnut, and of an irony nature. When distributed about upon the floor, table, or other level surface, within two or three feet of each other, they immediately begun traveling toward a common centre, and there huddled up in a bunch like a lot of eggs in a nest. A single stone, removed to the distance of three and a half feet, upon being released at once started off, with wonderful and somewhat comical celerity, to join its fellows; taken away four or five feet, it remained motionless. They are found in a region that is comparatively level, and is nothing but bare rock. Scattered over this barren region are little basins, from a few feet to a rod or two in diameter, and it is in the bottom of these that the rolling stones are found. They are from the size of a pea to five or six inches in diameter. The cause of these stones rolling together is doubtless to be found in the material of which they are composed, which appears to be loadstone or magnetic iron ore.

Electricity is the comparatively dormant power in nature. However, the philosophers and great inventors are on the scent. It is a force they are determined to utilize. Steam may give way to it even in this generation. It runs sewing-machines to-day, but the child is born who may see cars running at a fearful speed by that same agency. It is a motive power Nature employs in conducting the grandest operations in the heaven above and the world below.

REMONSTRANCE OF THE WESTERN UNION TELEGRAPH COMPANY AGAINST THE POSTAL TELEGRAPH BILL.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, February 13, 1872.

To the Honorable the Senate of the United States:

The Western Union Telegraph Company hereby respectfully remonstrates against the passage of Senate Bill No. 341, entitled, "A Bill to Connect the Telegraph with the Postal Service, and to Reduce the Rates of Correspondence by Telegraph," reported by the Senate Committee on Post-offices and Post-roads (Report No. 20), January 22d, 1872.

The following are some of the objections which we urge to the bill:

First.—Although the Report truly states that "the Western Union Telegraph Company performs nine-tenths of the telegraph business, and fairly represents the telegraphing system of the country," this Company has not been applied to by your Committee for any information either concerning its own business, or in relation to telegraphy generally; nor has it been offered an opportunity to be heard upon the subject before the Committee. On a single occasion, two years ago, the President of this Company was, on his own application, accorded a hearing before the Committee, limited to fifteen minutes.

Under these circumstances, the Managers of this Company have been much surprised at the publication, in a Senate document, of statements concerning this Company which are erroneous in fact, or in the inferences to be established, and which are used to justify the very extraordinary measures embraced in this bill.

This Company is not prepared to admit that the Senate of the United States is the proper tribunal before which to try corporations created by the States, either for alleged undue expansion of capital, unreasonable charges, or inadequate facilities; but we claim that, whether the measure reported by the Committee on Post-offices and Post-roads is based upon charges against this Company, or upon alleged considerations of public policy, the dictates of justice and the practice of the Senate, alike require an inquiry into the facts, and a careful investigation of the interests to be affected, before adopting legislation so important in its consequences. Representing, as this Company does in a large degree, the telegraph property, the telegraph experience and the telegraph progress of the country, we claim that, in any proposed legislation affecting telegraph property and business so vitally as the provisions of this bill, we are entitled to a hearing, both as to the necessity alleged to exist for Congressional action, and the effect of such action upon the private property involved.

We protest against the assumption of the Committee of the Senate, without proof and without having been heard in our defence, that the business of the Western Union Telegraph Company is conducted in disregard of the rights of the public to such an extent as to render it necessary for Congress to intervene. We are not advised that any person has applied to the Senate for the redress of any grievance alleged against this Company. Its Managers are believed to possess the confidence of the public, and are earnestly striving to meet their wants by extending their lines into new territory, and by enlarging telegraphic facilities as rapidly as the growth of business demands. The telegraphic facilities of the United States have been increased within less than six years past by the construction of thirty thousand miles of line and seventy thousand miles of wire, and the opening of more than three thousand new stations. Of this development the WESTERN UNION COMPANY has provided more than half, and has expended therefor about five million dollars, in addition to the contributions of Railway Companies included in its system, which amount to two and a half million dollars more. Probably the gross expenditure for new telegraph property by all the companies in the country, including railways, has amounted to nearly or quite, twelve millions of dollars within these six years. During this period the average charge for messages has been reduced one half, and work has been in progress for some time by this Company preparatory to further reductions, which will be made at an early day.

There have been paid in dividends to stockholders in telegraph companies, during the period of this development, about five millions of dollars, or an average of less than one million a year. This would be ten per cent.—the rate contemplated by this bill—on a capital of ten millions, which is less than the sum invested during the same time in extending and improving the telegraph system, which previously represented more lines and larger revenues than those for which Great Britain recently paid more than thirty million dollars in gold. That the capital invested in telegraphs in the United States is not now, and has not of late been receiving adequate compensation, is well known to all who are acquainted with the facts. The investment has been made, however, in the confident expectation of a suitable return as the country progressed in population and wealth. This Company has considered the ordinary risks incident to competing enterprises, where success depends on the patronage of the public, but they have wholly overlooked the possibility of danger from the Government, or of an attempt by Congress either to take their property or interfere with their business without just compensation, or to create a competing company, and then to confer upon that company the right of the exclusive use of the vast facilities provided for the postal service at the public expense.

Private enterprise has already established the telegraph throughout every State in the Union, and in all the territories but one (Arizona). The value of the services it has rendered, without charge in the interest of science, and to sufferers by fire, and flood, and pestilence, is far beyond that of all the pecuniary contributions it has received. Millions of acres of the public domain have been granted to railway corporations, while the telegraph has received no grants of land except whereon to plant its poles.

While the deficiency—nearly $25,000,000—in the revenues of the Post-office Department within the last five years has been defrayed by taxation upon the people, the extensions of the telegraph within the same period have been made by means of private capital, furnished by private citizens. This bill attacks the results of this enterprise, and, if it becomes a law, will be fatal to them.

Second.—This bill creates a corporation and confers upon the corporators special privileges and extraordinary powers. *Upon what principle, and for what reason the particular persons named in this bill are proposed to be made the recipients of a franchise never granted by Congress before, and of immense pecuniary value, in the event that they shall be enabled, under cover of its provisions, to grasp the telegraph property of the corporations created by the States, and now engaged in the business, we are not informed.* They are authorized to issue one million dollars of its stock "for expenses of organization," and as there is nothing in the bill to prevent the distribution of this stock among the corporators, we assume that to be their expectation. The bill contains no provision requiring the contribution of any money as the basis for the issue of such stock. The stock is entitled to receive dividends at the rate of ten per cent. per annum, so that Congress is, in effect, imposing a tax of one hundred thousand dollars a year, to be levied either upon the Post-offices or the senders of messages, to give a bonus to the beneficiaries under this bill, as an inducement to engage in a business in which they have now no investment, and in the conduct of which they have had no experience. If it be the policy of the Government to give so large a bonus to encourage investments in telegraphic enterprise, we submit that justice requires that companies now engaged in the business, and whose property is at hazard, shall at least be permitted to compete for the gift.

Third.—The bill provides that certain expenses, heretofore borne by telegraph companies, such as rent, lights, fuel, messenger and clerical services, and also for stamps, shall hereafter be borne by the Post-office department—the inference being that the necessary labor can be performed without increasing either the number of officials or the expenses of the department, and that it is on account of the saving thus effected that the telegraphic service can be performed by the corporation created by the bill at rates which all past experience in this country has found to be unprofitable. The fact that this illusive feature has escaped the scrutiny of the Committee on Post-offices and Post-roads is another evidence of the injustice of acting on the bill without subjecting its provisions to the criticisms of interested and competent experts. The bill provides for a class of messages (section 2) termed "registered telegrams," "which shall have priority of transmission," and on which double rates may be charged. On examining the Report of the Committee, to ascertain the reason for conferring a privilege of such immense value, we find no reference made to the subject.

This Company remonstrates against a scheme which gives a million dollars to create a new monopoly, under the pretence of checking an existing one, and which, under the plea of effecting "a greater reduction of rates than was obtained in Great Britain," covertly authorizes putting aside the ordinary messages of the public, whatever the pressure of their necessities, and giving up the wires to priority messages at double rates—the effect of which must inevitably be to establish the priority rates for all messages requiring immediate despatch. The priority rates under this bill are higher than the present average rate.

We remonstrate against the passage of a bill which proposes to hire out the Government Post-offices, furnished, and warmed, and lighted, and the services of Government *employes* to private parties, unless to the highest and most responsible bidder. Especially do we protest against being excluded from such competition, and being put on the defensive by those whose investments in the business will be made, if made at all, after they have realized from the gratuities which the bill proposes to confer.

Fourth.—The bill, in effect, exempts the property and business of the Company which it creates from State and municipal taxation. It also makes the Company the agent of the United States; so tha

Digitized by Google

the public would be as completely without redress, in case of neglect to forward and deliver messages, as they now are for the loss of registered letters and other valuables entrusted to the mails; at the same time all the risks of defalcations by postmasters and clerks, of theft or counterfeiting of stamps, are thrown upon the Post-office Department.

The Western Union Telegraph Company does not desire that the Government shall purchase their property. It has confidence in the future growth of the country in population, commerce and wealth. In the benefits of that growth the telegraph must largely participate. It relies upon the future for a just return for the great expenditure it has already made, and is still making, to enlarge and improve its service. If, however, this Company fails to meet the just expectations of the public, it is suggested that the true remedy is to require the surrender of its property, under the conditions of the law of 1866. But, until a state of things exists which makes interference by the Government necessary for the protection of public interests, this Company asks to be permitted to control and conduct its own business without Congressional intervention.

We remonstrate against the passage of this bill, because it would depreciate the value of the Company's property for the benefit of private parties. It cannot be that Congress would enact a law, the necessary and direct effect of which would be to depreciate the value of private property, which they have the right to purchase with a view to diminish the compensation to be paid therefor.

When the Company accepted the provisions of the Act of 1866, it was upon the assumption that a compact was thereby entered into between the Government and the Company—(1), that we were not to be interfered with by Congress until the expiration of five years; and (2), that thereafter we were only to be liable to be dispossessed of our property at a valuation to be fixed by arbitrators in whose appointment we should have an equal voice. This Company submits to the Senate whether the enactment of such a law as that reported by the Committee would not be a violation of the compact into which we entered, relying upon the good faith of Congress. Under that compact we are to-day transmitting messages for every department of the Government, giving them priority over all other business, at rates fixed by the Postmaster-General, which do not pay us for the cost of the service. Is it unreasonable in us to ask, as we now do, either that the compact be performed on the part of the Government or that this Company be released from its obligations?

Common justice requires that if Congress is to establish a competing enterprise, in which the Government is to be the active and only responsible partner, it shall leave this Company untrammelled by the restraints of a compact whose reciprocal conditions it wholly disregards.

The owners of telegraph property would be justified in petitioning Congress for relief from many of the burdens it is obliged to bear; but this Company asks nothing except a thorough investigation of the subject, at which they shall be permitted to answer any charges affecting their administration, and that they be allowed also an equitable participation in whatever privileges are offered by Congress with a view to making cheaper telegraphy possible.

The Western Union Telegraph Company relies upon Congress to protect their property from a scheme which, while it pretends to promise desirable reforms, and provides a princely bonus ostensibly to secure them, makes no provision either for compensation to the owners for private property virtually destroyed, nor for securing to the public any of the benefits promised them. We are unable to regard it otherwise than as a scheme to enrich its promoters at the expense of the public treasury, and of the private interests which it seeks to supplant.

WILLIAM ORTON,
HORACE F. CLARK,
E. D. MORGAN,
MOSES TAYLOR,
ALONZO B. CORNELL,
AUGUSTUS SCHELL,

Committee of the Board of Directors of the Western Union Telegraph Company.

CORRESPONDENCE.

RANDOLPH'S TELEGRAPH INSTITUTE.

NEW YORK, May 10, 1872.

To the Editor of the Journal of the Telegraph:

In establishing my Institute of Telegraphy in this city, with an experience of fourteen years as a practical operator, I can assure my patrons that they will receive advantages never before taught in a school of telegraphy.

My scholars will practice with the relay and local sounder, and not with the sounder alone, as is usual in all other schools.

The advantages are apparent to any practical operator. My wires and desks are so arranged as to make them represent a telegraph line and offices. By means of artificial appliances the various changes common to telegraph lines will be exemplified, and the student will receive information in this respect which is fully as important as the mere manipulation of the key in forming the alphabet, and without the knowledge of which would often times be unable to work themselves and prevent others from working.

I am authorized by the officers the W. U. Tel. Co. to state that all persons becoming my pupils, and who may creditably pass a board of examination, appointed by the above company, shall receive positions as operators, if at that time a vacancy should exist.

Very respectfully, K. S. V. RANDOLPH.

COUNTING FIGURES, IN DUPLICATE.

CORINNE, UTAH, April 22, 1872.

To the Editor of the Journal of the Telegraph:

Please inform us through the JOURNAL, how, according to the rules of the Western Union Company, "Twenty thousand dollars (20,000)" is counted.

It is contended that as the figures come *after* the word "dollars" they represent "twenty thousand dollars" and should be counted three words, making six words in all. H. *vs.* G.

Answer.—In counting figures in duplicate of words, the figures are to be counted as they are expressed in words. It is clear that "dollars" is not part of the figure, but is an article of which there are twenty thousand, in the sense given.

TRAIN DISPATCHING BY DOUBLE ORDERS.

XENIA, Ohio, May 7, 1872.

To the Editor of The Journal of the Telegraph:

As I notice considerable controversy in the JOURNAL of late, on the subject of "Train Orders," some correspondents claiming that it was impossible to use *double* orders in *all* cases, I take the liberty of sending you a circular, showing the system as at present used on this Division, which certainly covers *all* the contested ground. The system has been in use on the P. F. W. & C. Railway for years and is also in use on the Pittsburgh Division of this Railway. A. T. LEE,

Night Train Dispatcher, L. M. Division.

The first rule of the circular referred to by our correspondent, reads as follows:

"1. All special orders by telegraph for the movement of trains will be given in writing, addressed to the conductor. The conductor shall sign his name to the original order as written by the operator, who shall repeat it back, with the conductor's signature, with the prefix 'I 13,' to the office from which the order was received. The person sending the order will respond 'Correct,' followed by the exact time, which shall be endorsed on the order. The operator shall then make two copies of the order, adding thereto the reply 'Correct,' and the time following it, both of which copies shall be given to the conductor, who shall see that they are exact copies of the order signed by him, and hand one to the engineer. Both copies shall be signed by the operator.

Any engineer leaving a station under special orders, without a copy of the order in his possession, will be held personally responsible for all damage that may result therefrom."

DIRECT YOUR LETTERS PLAINLY.

BELVIDERE, N. J., May 10.

To the Editor of the Journal of the Telegraph:

Would it not be well to give notice through your columns that offices having error sheets between Belvidere, N. J., and Belvidere, N. Y., and also Ill., to have them plainly directed, as often letters belonging to Belvidere, N. Y., come to me and are opened before noticing the mistake, thus making extra postage. I have just received three belonging to Belvidere, N. Y., and have to forward them.

Respectfully, S. TUCKER, Manager.

THAT COLORED STUDENT.

ALTON, Ill., May 7, 1872.

To the Editor of the Journal of the Telegraph:

Do you think the operator who published in the JOURNAL of April 1 that I was instructing a young colored gentleman in the mysteries of the art, can meet me hereafter without compunctions of conscience for telling such a malicious and deliberate falsehood?

Yours truly, S. T. BAYLIES, Manager.

STUDENT, at Augusta, Ga., is informed that a person of quick perceptions is usually qualified for the business. That it requires perseverance and assiduity to excel. From three to five years constant application would probably bring him to the point known as first class Good operators are always in demand. Salaries vary, according to location, and position. Handwriting fair.

EX. OPR. at Tarboro, N. C., is informed that *good* operators are always in demand, in every section of the country. The market is over-stocked with the inferior article.

ONE OF THEM, at Detroit, will please accept our thanks for his attention. We already had the matter from another source.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, MAY 15, 1872.

SALUTATORY.

It is with extreme diffidence that the undersigned takes up the pen just laid down by his predecessor, and, with it, the duties and responsibilities imposed upon him by the kindness, and, perhaps, partiality of his superior officers.

The kindly feeling and geniality which the late Editor of this paper possesses in so remarkable a degree, and the universal feeling of friendship borne toward him by the fraternity at large, will tend to render the path of the present Editor the more arduous and difficult.

Under these circumstances, much should not be expected of him—certainly not at the present time. He has had but little experience, other than occasionally contributing to the columns of the daily Press.

Fresh from the ranks of the active toilers at the key and pen, he believes that he is familiar with their feelings, and is desirous that in the columns of the JOURNAL these feelings shall find vent; that not only shall this be regarded as the official organ of the Western Union Telegraph Company, but that it shall also be the organ of all employed by the Company.

The occupant of this easy chair finds it "easy" only so far as the seat is concerned, for there is plenty of work to be done, there being no place for idlers in the ranks of the Western Union Company.

If, when he lays down his pen and vacates the chair for some one more competent or more worthy, he shall receive only a tithe of the praise and evidences of good feeling, not only from his employers, but from all ranks in this noble profession, that has fallen upon the retiring Editor, his efforts will not have been in vain.

F. J. GRACE.

We would call attention to the advertisement of Mr. K. S. V. Randolph, in another column of this paper. Also to his communication in explanation of the special advantages enuring to the graduates of his institute.

Mr. Randolph is a capable operator, and has had considerable experience as a teacher. Those desirous of becoming telegraphers cannot do better than to enter into a few courses of study with him.

THE JOURNAL OF THE TELEGRAPH AND ITS AIMS.

During the latter part of the year 1867 the publication of the JOURNAL OF THE TELEGRAPH, in its present form, was resolved upon by the Western Union Telegraph Company, for three principal reasons:

First: That it should be the medium through which the various orders and changes, which, from time to time, became necessary in conducting the service, should reach those whose duty it was to carry them out.

Second: That it should indicate, to those interested, the general policy of the Company; and,

Third: That it should be the means of imparting knowledge and education in the art, to those in need of such instruction. The wisdom which resolved upon this publication is apparent.

Embraced in the general policy of the Company was the recognition of the fact that a perfect and just understanding between the officers and their employes was, in the highest degree, essential to the welfare of both.

Owing to a combination of unfavorable circumstances this understanding is not yet as perfect as it is desirable it should be. The mass of employes do not exhibit that perfect confidence in the Company which the Company deserve at their hands, and which they so greatly desire.

It is our mission to lay these facts and assurances before the operators of the country, and to ask their assistance and co-operation in securing the benefits to arise.

The Company desires to elevate the service. It is already equal to any, and superior to most, in intellectual ability. It can be carried still higher, but not while there are divided counsels. Every intelligent thinker must see that there is more in the business than a mere livelihood; that there are honors and emoluments, in the near future, for the deserving.

The business of the telegraph, under the auspices of the Western Union Company, has assumed such proportions that it is a power in the land, wielding a moral force which can be made irresistible. Every one connected with the business, from the highest to the lowest, has his part to perform. With the whole body a unit, one homogeneous phalanx, what limit can be set to their progress—the progress of mind? Each step taken in advance will be an advance of the entire body, and not of any individual portion.

In order to arrive at this position a mutual interchange of thoughts and ideas is of paramount importance, and there is no channel so appropriate for this purpose as the columns of this paper. Its columns are open to all. Suggestions from practical men are desired. Criticisms will be welcomed.

A standing rule of the Company requires that every one in its service should communicate, whenever in his judgment it seems necessary, any operation of a promulgated order, prejudicial to the interest of the Company. An operator's service is not complete with simply making and translating dots and dashes. The Company claims the benefit of the working of his mind, as well as that of his hand. And here it is that a superior mind attains its proper level. The earnest and thoughtful rise above the superficial, in their rise carrying the whole body a step forward. Honor will be given where honor is due.

Let us take the first step to this end. In the effort many will rise; many will remain, waiting only for another opportunity. Those, only, who lack the ability or the energy to keep in the race, will not find their condition improved. These will soon, from the force of circumstances, drop off, allowing the ranks to be more firmly closed, and the field for ambition enlarged.

A fruitful source of discord has its germ in the over-sensitiveness of many minds. Men sometimes imagine that they have been aggrieved; that they are oppressed by a superior officer. It is just possible that they may be correct.

Now, consider the proper means to place matters right and to secure justice. Is it to nurse an internal sulkiness; to retaliate by taking no interest in the business entrusted to them, or by any of the many ways in which retaliation is possible? Many take this course, not reflecting that such retaliation recoils upon themselves in the violence done to their own manhood—in the injury they inflict upon the *morale* of the *corps* and the direct injustice to the Company, which, probably, was not a party to the oppression, if oppression really existed outside of the sufferer's imagination. Some bolder spirit would, under similar circumstances, rush into print, in a quarter, where, owing to his diseased imagination, he derives comfort from a false sympathy. But in neither case is justice arrived at. One result, however, will have been attained; the whole body will have taken a step backward.

Would it not be better, if, instead of the course we have depicted, the aggrieved party should, if he cannot bring himself to the point where a personal explanation could be reached, communicate his cause of complaint to the JOURNAL, and thus, perhaps, in a friendly way, an apparent wrong might be made right. None need be apprehensive that confidence will be betrayed. If oppression really exists, there is a remedy, and the remedy will be justly applied, but there is no way to secure it other than the course we suggest.

Let it be understood, however, that we do not invite captious complaints, nor do we wish that our suggestions should be the means of fostering a state of chronic fault finding. Our chief desire is to second the aims of the officers of the Company in elevating the service, and to impress the truth, that the interest of employer and employé are identical; and when the JOURNAL becomes fully that for which it was established, the voice, not of one branch only, but of all connected therewith, the first step in accomplishing the desired result will have been taken. To this end we invite the hearty co-operation of all who, by advancing the interests of the service thereby promote their own.

REASONS WHY ALL TELEGRAPHERS SHOULD SUSTAIN THE JOURNAL OF THE TELEGRAPH.

Because it is a first-class journal, especially adapted, in its reading matter, to the wants of those interested in its speciality.

Because it is a handsomely-printed sheet, at all times with twenty-four, and occasionally with thirty columns of interesting matter.

Because it will, from time to time, contain instructive and entertaining articles upon the science pertaining to telegraphy, from the pens of leading scientists, both in this country and in Europe.

Because its columns are open to all to ventilate abuses and to suggest reforms.

Because it is at all times willing and anxious to impart information in the line of the profession, and there is none more competent.

Because, with all these advantages, its subscription price is so low—barely meeting the cost of the paper upon which it is printed.

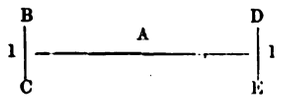
TO OUR SUBSCRIBERS.

In examining the subscription list of this paper, we find that many of its nominally paying subscribers are greatly in arrears. The paper is honestly worth more to any telegrapher than the price charged for it, and the amount is so small that it is within the means of all.

In this view, is it not inexpressibly mean for any person to continue receiving the paper without remitting its subscription price?

The number of backward subscribers is so large that we cannot undertake to present a bill to each one, so we here appeal to every one knowing himself to be in arrears to settle up for the past, and subscribe for the present and future volumes.

As the rate of subscription is invariably payable in advance, the JOURNAL, after the present number, will be sent to those only who have complied with its terms.



WE are pleased to hear of the appointment of Mr. W. H. Sawyer, as General Superintendent of the American District Telegraph Company.

Mr. Sawyer is in every way qualified for the position. His appointment is another exemplification of the reward which surely follows merit and faithful performance of duty.

WILL water burn? And if so, can burning water be used at a moderate cost for fuel? The public mind of Peoria, Ill., has been of late much exercised upon these questions. A stranger and a Yankee came to the city and claimed that, by burning mixed water and oil in it, he could heat a common cooking stove red-hot in five minutes. The proportions were four gallons of oil to five gallons of water, and with this quantity the inventor declared that he could run a steam-engine for thirty days, heat twelve furnaces, or light a whole city with gas. The oil was worth fifty cents a barrel, and cooking, heating and lighting were thus to cost almost nothing. A stock company was started to push the enterprise, and it was found that, "by the aid of twelve gallons of oil, two gallons of water could be evaporated." It didn't promise overwhelming dividends. The corporation disembodied itself as fast as possible, and the inventor, packing up his gas-pipes and oil-cans, left Peoria to enlighten and warm some other region.

This almost equals Paine's "Water Gas" and his latest exploit in electro-motives. He had better look to his laurels.

DOUBLE TRANSMITTER.—The Western Union Telegraph Company has acquired the exclusive ownership of the patents of 1868 of Joseph B. Stearns, of Boston, Mass., for instruments by which telegraph messages are transmitted in opposite directions by the use of a single wire. This improvement is one of the most important that has been made in connection with telegraphy. Many of the Stearns instruments are now in use, and the Western Union Company is introducing them upon its lines as fast as they can be manufactured. The importance of the invention will be understood when we state that it practically doubles the transmitting capacity of every telegraph wire owned by the company. Let none of our readers suppose that the chimera of "sending two currents in opposite directions on the same wire" has been realized in this invention. Not that; but its practical equivalent is realized, to wit: Two messages are transmitted simultaneously in opposite directions by means of one wire while the electrical current is always moving in one circuit, in the usual manner. How it is done we tell by means of this simple diagram:

A is the wire stretched between the two places, say New York and Boston; 1—1 the tables on which are the instruments in the offices at either end of the line; B the receiving instrument at New York; C the sending instrument do.; D the sending instrument, and E the receiving instrument in the office at Boston. A sending and a receiving operator sit at the opposite ends of the same table in each office, and from each instrument—four in all—a ground wire descends to the earth, thus making two complete circuits over the single line. The operator at B pays no attention to what his co-laborer at C is doing, but sends right through to D, and at the same time E is sending to C, or *vice versa*, neither interfering with the other in any manner.

We shall, on a future occasion, probably illustrate and fully describe this marvel in telegraphy.

ELECTRIC EARTHQUAKES.—A frantic scientist has discovered at last the cause of California's shocking earthquakes. It is all the fault of the mineral belts constituting the slopes of the Sierra Nevada. Iron predominates in all these belts, and as iron is the most obliging conductor of electricity, they become in the dry season immense reservoirs of confined negative electricity. Dry air being a non-conductor, all this force gets no chance for equalization with the air current, hence, when it becomes crowded, it bursts out with tremendous impetuosity. To check this agitating performance, our savant advises the use of iron conductors. The trembling Californians listen kindly, and lonely horsemen, winding down the great hills of the Sierra Nevada range, may presently prepare to see them surrounded by an expensive and bristling fence of lightning-rods.

BORN.

GRIFFEN.—April 20th, 1872, to F. P. Griffen, Manager W. U. Telegraph Office, Upper Sandusky, O.; a daughter.

VANAKIN.—To L. S. Vanakin, Manager W. U. and Erie Railway Telegraph Office, Lackawaxen, Pa.: a son.

SMITH.—May 2, 1872, to Robert H. Smith, W. U. Telegraph Office, Baltimore, Md.; a son.

MARRIED.

BOLDON—COFFEE.—At Visalia, Cal., April 18, 1872, by the Rev. Mr. Kinkade, J. J. F. Boldon, Manager of the W. U. Telegraph Office, Emigrant Gap, to Miss Matilda N. Coffee.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
May 15, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since May 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

* Beatrice, Neb.,	500 Mexia, Texas,
863 Byram, Miss.,	866 No. McGregor, Iowa, Heretofore an other line office.
448 Carthage, Mo.,	
428 Concordia, Mo.,	
337 Cornland, Ill.,	299 Perrysville, Ind.,
* De Witt, Neb.,	201 Port Clinton, O.,
Greensboro, Ga., reopened,	* Shelby Iron Works, Ala.,
366 Harpers Ferry, Iowa,	18 So. Weymouth, Mass.,
437 Higginsville, Mo.,	384 Tangipahoa, La., re-opened.
366 Lansing, Iowa,	363 Terry, Miss., re-opened.
299 Montezuma, Ind.,	

NEW OFFICES ON OTHER LINES.

Beatrice, Neb.,	105	7	Plattsmouth, Neb.,
DeWitt, Neb.,	95	7	" "
Shelby Iron Works, Ala.,	50	5	Columbia. Ala,,

OFFICES CLOSED.

Barclay, Ill., Brandon, Miss., Cash-Up, Pa., Harmsburg, Pa., Maywood, Ill., and Weaverton, Md.

GENERAL INFORMATION.

Letters for the following offices should be mailed as indicated herewith:

Aqueduct, Pa.,	Duncannon Co., Pa., P. O.
Eagle, Pa,	Spread Eagle, Chester Co., Pa., P. O.
Bigler, Pa.,	Williamsgrove, Clearfield Co., Pa., P. O.
Julian, Pa.,	Julian Furnace, Pa., P. O.
Mifflin, Pa.,	Paterson, Juniata Co., Pa., P. O.
Osceola, Pa.,	Osceola Mills, Pa., P. O.
Perrysville, Pa.	Port Royal, Juniata Co., Pa., P. O.
Petersburg, Pa.,	Shavars Creek, Huntington Co., Pa., P. O.
Rockville, Pa.,	Susquehana, Dauphin Co., Pa., P. O.
Sandy Ridge, Pa.,	Powelton Centre Co., Pa., P. O.
Snow Shoe Intersection, Pa.,	Milesburg, Pa., P. O.
Steamboat, Pa.,	Glenlock, Chester Co., Pa., P. O.
West Chester Intersection, Pa.,	Paoli, Co., Pa., P. O.

The name of the office heretofore known as Chapmans Creek, Kansas, has been changed to Chapmans, Ks., and that of Harlem, Cook Co., Ill., changed to Oak Park, Ill.

Hereafter the "Tariff for other lines" to Clam Lake, Mich., will be 65 and 4, and to Leroy, Mich., 55 and 4 from Grand Rapids, Mich.

Offices which have recently received new rates to Pittsburgh, Pa., will charge 15 cents more than Pittsburgh, Pa., for tariff to Birmingham, Pa.

WILLIAM ORTON, Pres't.

TRANSFER SERVCE.

EXECUTIVE OFFICE,
NEW YORK, May 15th, 1872.

The following changes will be made in the list of transfer offices on May 20th, 1872:

New Transfer Offices Opened.

Mount Carmel, Pa.—D. H. Bates.
Schuylkill Haven, Pa.— do.

Transfer Office Closed.

Meridian, Miss.—J. B. Tree.

OCEAN TELEGRAPH.—The Great Western Telegraph company, which intends laying a telegraph cable from New York to England, by way of Bermuda, has paid the Messrs. Hooper, who are manufacturing their cable, the first instalment of £100,000.

Telegraphers'

Mutual Life Insurance Association.

INCORPORATED UNDER THE LAWS OF THE STATE OF NEW YORK.

I. This association shall be known as the Telegraphers' Mutual Life Insurance Association, and be organized under the general State law of the State of New York.

II. Its officers shall consist of a Treasurer and Secretary.

III. There shall be an Executive Committee of five, of which the Treasurer and Secretary shall be members, who shall exercise a general supervision over the affairs of the association and decide all questions which may arise.

IV. No officer shall, at present, receive any remuneration for his services.

V. No expense of any kind will be allowed except for expenses of incorporation, stationery, postages, circulars, certificate and advertising.

VI. Any person, regardless of sex or class, may become a member of this association provided they are or have been employed in the telegraph business and subscribe to these articles, and are unobjectionable to the Executive Committee.

VII. The initiation fee shall be one dollar and fifty cents, one dollar of which shall go to the contingent fund, and the balance to the expense account.

VIII. Upon the death of a member the Treasurer shall immediately, on application by the proper parties, pay over to them the fund which is on hand for that purpose, that is, the whole of the contingent fund on hand from the previous assessment.

IX. It shall be the duty of each member of this association to leave in writing, the name of his or her executor or heir, failing to do which the amount of insurance shall be used, first, to pay the expenses of burial, and the balance to be given to such relations of the first degree as are dependent on the deceased, or should there be none such, to be subject to the disposition of the Executive Committee for the benefit of the association.

X. Immediately on the decease of a member, the Treasurer shall assess each remaining member $1, payable within thirty days of the issue of the assessment call, neglecting to pay which during the time specified, the delinquent shall forfeit all claims to membership or the benefits of the association, and he shall be restorable only on the unanimous vote of the Executive Committee and the payment of dues.

XI. A meeting for the election of officers shall be held annually during the first week in November in each year, who shall be elected to serve for one year or until their successors are elected. In case of the death of a member of the Executive Committee the remaining members shall have the power to fill the vacancy until the time of the annual election.

XII. Special meetings of the association may be called upon the written request of twenty-five members.

XIII. It shall be the duty of the Treasurer to receive all moneys, sign receipts, and pay bills and claims when audited by the Executive Committee. He shall give suitable bonds for an amount equal to twice the amount of money on hand at the time of his election.

XIV. The Secretary shall keep the records of the association, maintain such correspondence as is necessary with members, and issue such notices as may be necessary. He shall also aid the Treasurer in all matters in which he may require assistance.

XV. Certificates of membership shall be given, signed by the Treasurer and Secretary.

XVI. The books of the association shall always be open for examination by any member thereof.

A. S. BROWN, Treasurer.

W. K. APPLEBAUGH, Secretary.
A. B CHANDLER,
GERRITT SMITH,
D. R. DOWNER,
Executive Committee.

DIRECTIONS TO APPLICANTS.

1. The number admissable as members of the Association at any one time, having been limited for the present to *fifteen hundred*, it is necessary to apply early if membership is desired.

2. Apply by letter, *enclosing one dollar and a half and a three cent postage stamp for each application*, to Gerritt Smith, Secretary Telegraphers' Mutual Life Insurance Association, 145 Broadway, New York, and a certificate of membership will be sent by return mail.

3. Every applicant must be known to the Executive Committee, or to some responsible Manager of a Telegraph Office, and evidence of this, and of good character and of ability to work, must accompany each application. The endorsement of a reputable Manager will be regarded as denoting eligibility as stated, and the signature of the applicant, with date, amount and recommendation, will be all the form of application necessary.

4. Each applicant must file with the Secretary written directions respecting the disposition of the money to which he or she may be entitled at death.

5. No letters can be answered unless a stamp is enclosed for postage; and as the officers labor without compensation, correspondence requiring answers should be as limited as possible.

JOURNAL OF THE TELEGRAPH.

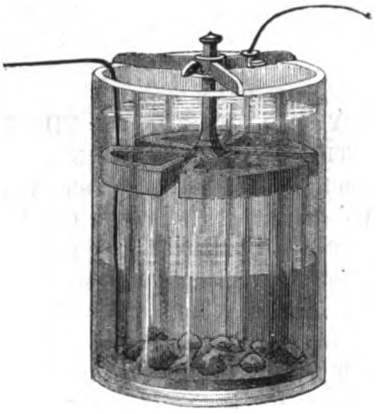
VOL. V. NO. 13. NEW YORK, JUNE 1, 1872. WHOLE NO. 110.

THE CALLAUD BATTERY.

In consequence of the inconvenience experienced in the use of the Daniell battery from the deposit of copper upon the porous cell, M. Callaud, a clock-maker at Nantes, France, endeavored to discover some process by which it could be suppressed altogether without diminishing the force of the battery or lessening its constancy. In this effort he was entirely successful, for after a series of experiments he found that the difference in the density of pure water, or water charged with sulphate of zinc, and a solution of sulphate of copper, was sufficient of itself to cause an entire separation between them when placed in the same vessel. Accordingly he constructed his battery by suspending a cylinder of zinc near the top of a glass jar, and placing a copper plate at the bottom, and then filling the jar with a saturated solution of sulphate of copper and a diluted solution of sulphate of zinc. The difference in the specific gravity of the two solutions causes them to separate at once and become superposed in the jar, the sulphate of copper occupying the lower and the sulphate of zinc the upper portions of the jar.

The chemical action which takes place in this battery is the same as in the Daniell. The zinc cylinder is oxidized by the oxygen of the water, and the oxide combines with the acid set free by the solution of sulphate of copper, forming sulphate of zinc, which remains in solution, while the oxide of copper, which was previously combined with the acid, being set free, is reduced to metallic copper, and is precipitated on the surface of the copper plate at the bottom of the jar. The reduction of the oxide to the metallic state takes place in the following manner: The water of the solution furnishes oxygen to the zinc, and thus enables it to combine with the acid; while the hydrogen, which is liberated, again forms water with the oxygen of the oxide of copper, with which it comes in contact, leaving the metal free. Hence but little gas is given off during the action of a battery charged by sulphate of copper, as the hydrogen is in this case mostly absorbed.

When all the sulphate of copper has been decomposed the action ceases, and sulphate of zinc will be reduced upon the copper plate as a black powder. It is necessary, therefore, to provide a constant supply of sulphate of copper. A few crystals of sulphate of copper should always remain in the bottom of the jar undissolved.



When the water in the upper portion of the jar becomes saturated with sulphate of zinc, the sulphate crystalizes upon the zinc plate, stopping the action of the battery. The conducting power of a solution of sulphate of zinc is greatest when diluted with an equal quantity of water. Part of the solution should, therefore, be from time to time removed and replaced by water.

When crystals form on the top and sides of the cell, in consequence of the water being charged with sulphate of zinc, they should be removed with a damp cloth.

The bottom of the zinc cylinder should be four inches from the copper plate.

Half a pound of sulphate of copper is sufficient to charge a fresh cell of the Callaud battery, and to leave a portion of the crystals undissolved. A pint of water, at the ordinary temperature of the atmosphere, is capable of dissolving one-quarter of a pound of blue vitriol

In starting a fresh Callaud cell it is better to use a small quantity of the sulphate of zinc solution taken from some other battery, but if this cannot be readily obtained, a solution of Glauber's salt (sulphate of soda), or even common salt (muriate of soda), will answer. It is not necessary, however, to use any thing but common water. In this case the two poles of the battery should be connected together in short circuit for a few hours, when it will make its own sulphate of zinc solution.

The above cut represents an improved form of the Callaud battery, recently designed by Mr. Phelps, which is to go into general use upon the lines of this Company, in place of the bi-chromate of potash and nitric acid batteries.

HIMMER'S IMPROVEMENT IN ELECTRIC BATTERIES.

The improved battery which forms the subject of the present notice is the invention of Vitalis Himmer, of the city of New York, and it is claimed that the arrangement employed permits the power to be regulated at will, and that a supply of its source of power can be attached to it to keep it operative for a length of time practically limited only by the supply of the material. The battery cup is made of glass or other suitable material. A small vessel of truncated conical form is placed upon the bottom of the battery cup. A vessel of suitable size and shape is filled with sulphate of copper and water, and provided with a neck, through which a small tube is fitted, this tube being preferably held in a cork, in which it may be shifted up and down and still held secure. This vessel is inverted, and placed upon the battery cup, so that its tube enters the truncated conical pot, placed in the battery cup, to a greater or less depth. The copper element of the battery is placed in this pot. The zinc element of the battery is placed within the upper part of the battery cup, and held there by its own spring pressure.

The outside battery cup described being filled with salt water, the vessel holding the sulphate of copper and water is inverted over the cup, its tube entering the pot. The upper end of the tube is preferably closed; and small perforations are cut near the top through it, so that they will not be liable to become clogged by pieces of sulphate of copper. The water in the inverted vessel will gradually dissolve the sulphate of copper, the solution flowing into the pot containing the copper element, where, on account of balanced pressure, it will rise no higher than the lower end of the tube. That amount of surface of copper which is in actual contact with the above-named solution will be active in the battery, but not the remainder. The depth to which the tube is immersed, and the consequent height of the sulphate of copper solution, determine, therefore, the strength of the battery. The zinc will, by the contact with the water, always be ready for action, the spent zinc dropping to the bottom of large battery cup, but not into the pot containing the copper element.

When the battery is active, the solution in the latter will be gradually absorbed and a new supply constantly given down in such ratio as is necessary to provide the active effectiveness of the battery. When the battery is not used there will be no displacement of solutions. The cup containing the sulphate of copper and water may be secured upon the battery cup in such manner as to secure it air tight, in which case evaporation is absolutely prevented. A battery of this kind can, it is claimed, be kept in effective operation continuously for years, without requiring the least addition or replacement of parts, provided the copper and zinc are of sufficient size, and the supply vessel large enough to hold the requisite amount of the sulphate of copper.

THE TELEGRAPH DURING THE CINCINNATI CONVENTION.

Every one acknowledges that the telegraph is a wonderful arrangement for transmitting news. The wires were taxed to their utmost extent during the session of the Convention which has just closed its labors in this city, resulting in the nomination of Greeley and Brown for President and Vice-President of the United States, and the quantity of news transmitted is almost incredible. It has been ascertained that *six hundred thousand words*, or an amount equal to about *three hundred columns* of the *Enquirer*, were sent by the indefatigable correspondents and the Associated press during the Convention to the various newspapers of the country. It will thus be seen what can be done in an emergency by the telegraph, and also what a demand there is on the part of the public for news.—*Cincinnati Enquirer.*

LIGHT, HEAT, AND ELECTRICITY FROM MOTION.

The celebrated Jacob Perkins, when in London, in 1887, exhibited at the Adelaide Gallery the phenomena produced by the contact of soft iron with steel in motion, and which he described at the time as follows:

"The action of a soft iron disk upon hard steel, such as a file, is exhibited four times a day. This has been regularly kept up for three years, yet it has undergone very little wear. I am of opinion, in fact, that if the file had never been held upon it until it had attained its full velocity, there would not have been any loss of metal. I do not know to what extent the combustion of steel by soft iron may have been carried in the United States, but our experiments are so brilliant as to excite the highest admiration, and to induce numbers to repeat their visits to the Gallery. Our disk is a foot in diameter, and an eighth of an inch thick. It requires about a three-horse power to drive it, and revolves about 6,000 times in a minute. It is very accurately fitted up with friction wheels. The blaze of light, which rises about twelve inches, perpendicularly, from the point of contact, is so vivid that few persons can look steadily at it even at noon day. The stream of light is about an inch and a half thick at the distance of a few inches from the point of contact; and at the distance of seven or eight feet, it spreads out to about ten inches. The sparks not unfrequently touch the ceiling, which is about twenty feet high; a ring of fire is seen all around the disk, appearing like a band of light about five-eights of an inch wide. Of what does this light consist? It is manifestly different from that of the sparks, which all fly off in a tangent. In operating with the disk, it never becomes warm; the file, however, has to be held at least two inches from the sharp end, as it becomes highly heated. The whole appearance, in fact, is very interesting, and when fully investigated, I am well convinced that some of the phenomena will be found to depend upon electricity."

SURFACE ELECTRICITY.

It is well known that Faraday made numerous experiments upon this subject, and has varied, under different forms, that which Coulomb has realized with the hollow sphere and its two covers. It is still under this form, the least commodious, that this experiment is repeated in the lecture room.

If the loss is considerable on the day when this experiment is performed, it ceases to be sufficiently conclusive; for it requires, first, to electrify the sphere alone; second, to recover it rapidly with its two covers; third, to take them off; fourth, to prove that these covers are electrified; and fifth, that the sphere is not. The second operation cannot be executed with great rapidity, on account of the form of the covers.

Amongst other experiments, Faraday has made the following: He took a cylinder made of metallic gauze, placed upon an insulated horizontal metallic disk, the design being to afford proof that the exterior is alone electrified. An animal, such as a mouse, placed in the interior, showed no commotion, even when the whole apparatus was electrified so strongly that bright sparks might be obtained from it.

Faraday did more: he constructed a cubical chamber twelve feet on each side, with laths, the walls were of wire gauze and of paper, and the whole chamber was suspended by means of silken ropes. The chamber, even the interior could be electrified ngly on connecting it with an electric machine. Faraday inclosed himself in this chamber, with electroscopes and various other apparatus, but he failed to find the least trace of electricity, whilst the walls were so strongly electrified that vivid sparks were obtained from the outside, and "brushes" escaped spontaneously.

M. Terquem has endeavored to repeat this experiment in his lectures, on a small scale, in the following manner: He took any form of bird cage, whether of wood and iron wire, or entirely of metal, and suspended it to some isolated conductor in communication with the electric machine. Inside the cage was placed a gold-leaf electroscope, and also pieces of tinsel, the feather of a quill, and pith balls. Whilst it was possible to obtain vivid sparks from the cage, nothing moved in the interior. Within the cage was suspended a bundle of linen yarn, and underneath the cage a similar bundle; the interior bundle remained undisturbed, whilst the exterior was greatly excited and electrified, all the bits of yarn spreading out, and on approaching the hand the peculiar cracking due to electricity was heard.

Bands of paper being stuck along the length of the wires of the cage, the exterior bands would twist strongly and get displaced, whilst the interior remained vertical and unmoved when the cage was electrified. To complete the experiment, a bird might be placed inside the cage, and by his singing and general demeanor prove that he was not only completely indifferent to the phenomenon of electrical charge and discharge, but that behaving so proved that the interior of the cage was perfectly free from all electrical phenomena, whilst the exterior alone was susceptible to the electrical influences. —*Engineering.*

QUANTITY AND TENSION OF THE ELECTRICITY OF A CURRENT.

The quantity of the electricity passing in a current, or the strength of the current, (Fr. *Intensité*, Ger. Stromstärke), is estimated by the power of the current to deflect the magnetic needle, by the chemical decomposition it effects, or by the temperature to which it raises a wire of given thickness and material. The strength of the current must not be confounded with the strength of the cell or battery which gives rise to it. A battery of one hundred cells, is, undoubtedly, a stronger electric arrangement than one cell, yet in certain circumstances, the one cell will give rise to as strong a current as the hundred. The force of the battery, sometimes called the tension of the current, is the power which it has to transmit a current against resistance, such as that offered by a bad, long, or thin conductor. Tension, strictly speaking, is not a property of the current, but of the battery which generates the current; it is a statical property, and is exhibited by the insulated poles of the battery. A current of high tension is one which is maintained by a battery, whose poles exhibit high tension. The tension of its poles is a measure of the electro-motive force of the electro-motor, (*i. e.*, any arrangement such as a cell or battery which generates a current, sometimes also rheomotor). By electro-motive force is understood the power to keep electricity in motion, or to maintain a current against resistance. The electro-motive force of any cell or battery may be measured before the circuit is closed, by connecting the zinc or — pole with the ground, and the insulated copper wire or + pole with a condensing electromoter, and observing the amount of statical tension—*i. e.*, attraction or repulsion produced. The tension, so measured, gives the power of the arrangement to propagate electricity. When the circuit is closed, the electro-motive force is ascertained, as already mentioned, by introducing new resistance into the circuit, and observing the effect produced on the strength of the current. *The electro-motive force of the pair is proportional to the intensity of chemical affinity or the force tending to chemical action, the current strength to the amount of this action or quantity of zinc dissolved in a given time, and the resistance is that which prevents the former from developing the latter.* Tension, when high, is also measured by the length of the spark.

ELECTRO CHEMICAL COPYING PRESS.

This press, the invention of Signor Zuccato, of Padua, Italy, differs but little in appearance from an ordinary copying press, and that difference lies mainly in the construction of the upper and lower beds or surfaces of the press, of which the former consists of a plate of copper, and the latter of a plate of copper tinned, both on mahogany beds—the upper one being attached by lugs or clips to the solid iron press plate, and the lower being made to slide out as shown. These plates are placed in the ordinary way in the circuit of a battery, so that when brought in close proximity by the action of the screw, the circuit is completed and a current established over the whole of the surfaces.

But, by the aid of an insulating medium—a varnish—applied to a steel plate and removable by the action of a "style" in writing, printing, drawing, etching, etc., the electric current is confined to those portions only which are so denuded of the insulating protection; and here it is made to leave record of its passage by its continued action on the steel plate and sheets of copying paper specially prepared and damped with a solution of prussiate of potash. The electrolytic action causes the formation of the ferro-prussiate known as the "Prussian blue." producing a perfect fac simile of the original manuscript or design wrought on the varnished surface of the plate.

The battery employed consists of a single cell, with zinc and carbon elements in an actuating solution of bichromate of potash and sulphuric acid; and its positive and negative poles are connected in the usual way, by spiral coils of insulated wire, with the upper and lower beds of the copying press. The moveable steel plates, on which the writing drawing, or other design to be copied, is made, has to be thoroughly cleaned and well and evenly varnished; care also must be taken, by a firm, steady pressure on the style, effectually to remove the varnish, leaving the writing, printing or other pattern, in bright steel on a raised ground of varnish, affording perfect insulation everywhere else on the surface.

By placing the copying sheets, efficiently damped with the prussiate solution, in any number from one to five or six, one over the other, superimposed on the prepared plate, a corresponding number of copies can be obtained, and so on, almost *ad infinitum.* Thus any required number can be produced with perfect facility and ease—all being fac similes of the original.—*Mechanics' Magazine.*

ACOUSTIC TELEGRAPH.—Professor Weinhold, of Chemnitz, Germany, has invented a phonic telegraph, employing neither electricity, magnetism, light or heat. The wire, which must be very carefully insulated, is attached at both ends to sounding boxes. Words uttered near one sounding box are repeated by the other very distinctly. This telegraph has been found to work well on the short line (2,200 feet long) where the experiment was made.

THE METRIC SYSTEM.

A movement now slowly but surely gaining groung among statisticians and men of science, is that which tends to the unification of weights and measures all over the civilized world, and—presumably—the adoption of the French metric system. "What," the gentle reader may ask, "*is* the metric system?" Briefly this: The circumference of our earth, measured on a meridian of longitude, is, in very rough figures, about 24,000 miles—a quadrant, therefore, or distance from pole to equator, 6,000. These 6,000 miles contain, evidently, some 30,000,000 feet, of which one ten-millionth part would be three feet—one yard. Accurately calculated, this quantity is 39.37 inches, and has been adopted since the beginning of this century by the French and several other European governments as the basis of their system of measures, under the name of *metre*. Let us, for convenience sake, call this metre forty inches, and see what further comes of it. A hundredth part of it, the *centimetre*, is just about four-tenths of an inch, and is used in France for all smaller calculations in the fine arts and manufactures; while scientific men, with their minute computations, are familiar with a tenth of this—the *millimetre* and its decimal subdivisions. Railroad men and surveyors use a thousand such *metres* under the Greek title of *kilometre*, a little over 3,000 feet, or six-tenths of one mile. These are the familiar units of length; now for measures. Let the reader be good enough to take—or imagine—a little cubical box, one *centimetre* (.4 inch) in cube, filled with distilled water at the temperature at which it reaches its maximum density. The weight of such water gives the unit of weight, the gramme—about 15½ of our grains. By the same consistent system of Greek and Latin nomenclature, a hundredth part of one of these *grammes* gives the *centigramme*, for chemical analysis, druggists' work, etc.; and a thousand grammes gives the kilogramme—or rather more than two of our pounds—for the grocers' sugar and butter, and the manufacturers' heavy materials. Next for liquid measures. Take, as just now, a thousand of these little *gramme* boxes, piled solid, or, what is better, the space they would occupy, and we have a new cube—one *decimetre* in length, breadth, etc., whose contents in distilled water evidently weigh the *kilogramme* aforesaid. The *capacity* of this box, however—as nearly as possible sixty-four cubic inches—makes the French *litre*, or unit of fluid measure—a liberal English quart. If we are doing a wholesale business in fluids, we may need the *hectolitre*, or hundred-quart measure. For dry measure we take a cubical box just one *metre* each way, and have the *stere*, roughly stated at thirty-five cubic feet. Marketing, evidently, would be best done by the *decistere*, or 3½ feet cubic. Housekeepers, who know better than we how much space a peck of peas or tomatoes takes up, will please make their own calculations. And finally, when the farmer wishes to buy land, he takes a ten-metre pole, and the square of which this forms the side is his *are*—about 120 square yards. One hundred of these *ares* give him his ordinary unit of measure, the *hectare*, or two and a half acres.

All this is a little complicated, and needs some figuring, but, apparently, we will have to come to it some day, and might as well begin now. Our young friends—and some older ones—will find it worth while to cipher it out for themselves a bit, over the parlor fire. It will be noticed that the Greek terms run *up*, in multiples, and the Latin ones *down*, in fractions, and that we make no mention of intermediate terms—*decagrammes*, *hectometres*, etc., not actually much used, if at all.—*Scribner's for June.*

THE BOUNDARIES OF SCIENTIFIC KNOWLEDGE.

The lecture on "The Scientific use of the Imagination," delivered by Professor Tindall in Liverpool before the British Association, harps upon a subject which also claimed the attention of Professor Huxley, Mr. J. Clerk Maxwell, F.R.S., and Professor Roscoe, F.R.S., in their respective presidential addresses. All of them expressed the desire to see more of the constitution of common matter than the microscope is competent to reveal. All the leading philosophers of the day agree, perhaps without an exception, that light consists of wave motion of the interstellar ether, the evidence being now irresistible, but they are not so well agreed that common matter consists of vibrating rigid atoms. Professor Tyndall brought one splendid idea to bear with great force on the latter subject. He said, in effect, that when waves of sound strike the ear, if we trace those waves to their origin, we always come to a vibrating string, or tongue, or substance, originating the impulses in the air. When mechanical waves of light strike the eye, if we trace out those waves to their origin, how can we expect to find anything but substantial vibrating particles producing the wave motion? Again, it is absolutely certain that the components of common matter, whatever they may be, are in constant motion.

Helmboltz demonstrated by mathematics that if a "perfect" fluid—that is to say, a fluid destitute of viscosity or fluid friction—were once thrown into a state of vortex motion, it must of necessity preserve that motion to all eternity. Sir William Thompson, taking up this idea, suggested that atoms might be vortex rings of that nature. He and Professor Tait then devised a very remarkable experiment. As they could not get command of a perfect fluid they were obliged to choose an imperfect one—common air—and then they found means to throw it into vortex rings. They took a large square box, and cut a hole as big as a cheese plate in one end; they then cut the opposite end of the box away entirely, and tied a cloth on in its place. Then every time they banged the cloth with the hand at one end of the box, a vortex ring of air was driven out at the other. How were these rings to be made visible to the eye? They filled the box with white smoke, by allowing hydrochloric acid gas to enter the box through one little hole in the side, and ammoniacal gas in excess to enter through another; when these two gases mixed, they formed a dense white smoke, so that every time the cloth was struck, out flew a vortex ring of air, holding white smoke in suspension. The white ring floated about the room, and lasted for some little time, but, air not being a perfect fluid, they finally melted away. It was a curious sight to see two of these rings come into collision in the room, for then they rebounded from each other like india-rubber belts.

This article is headed "The Boundaries of Scientific Knowledge," and there is another field of mystery which enters much into the consideration of the philosophical mind, but which was not brought under the notice of any section of the British Association. That subject is the numerous instances in which solid objects rise or float in the air by some force having no weight of itself, yet competent to overcome the attraction of gravitation. Professor Tyndall recently exhibited a case of this kind at the Royal Institution, when he showed two little fishes cut out of gold leaf quivering in the air near the knob of a charged Leyden jar. What held those fishes there? "Electricity," is the ready reply. Yes; but electricity has no weight, so here is a clear case of a "something" without weight supporting in the air metallic gold, one of the heaviest of the metals. The said "something" was also invisible by daylight, though had the light been shut out a beautiful brush-like electrical discharge would have been seen emanating from the pointed tails of each of the two fishes. Magnetism likewise as everybody knows, will cause a piece of iron to rise in the air in opposition to the attraction of the earth, and this phenomenon is at the present time perfectly inexplicable by the man of science.

A very interesting experiment connected with this subject was recently performed at the telegraphic soirée given at the house of Mr. John Pender, on the occasion of the opening of direct electrical communication with India; the Prince of Wales, it may be remembered, was present on the occasion. As the experiment is a new one, and the details have not as yet, we think, been published in any journal, it may be of interest to many men of science if we publish them here. Lord Lindsay had at the soirée an enormously powerful electro-magnet, with adjuncts to facilitate experiments in diamagnetism. The poles of the magnet were square and two inches across, and when a half-crown was allowed to fall through the air, between these poles, it took four seconds to fall through the two inches of space containing nothing possessing weight, except common air. This is a common enough experiment, but Mr. C. F. Varley, C. E., the electrician, devised a novel experiment to show that the magnetic rays do not hold up the half-crown, but generate electrical currents to produce the effect. He had some copper wires bent into rings and soldered together; the wire was 1-16th of an inch in diameter, and the ring 1¼ in. These rings were seven seconds in falling through the two inches of magnetism, but on breaking the soldered junction, and thus preventing the well-known formation of electrical currents therein, the ring fell through the space very rapidly. Mr. Varley concludes that this experimeut proves "that a current of electricity is as solid and material to a magnetic field as is a plate of iron to a bar of copper." The general subject of the suspension of solid substances in the air, in opposition to the attraction of the earth, and by invisible forces, or perhaps substances having no weight of their own, is worth consideration in one of the sections of the British Association next year.

OCCASIONALLY we fall on some statistics which carry a real meaning to them; and the prosperity of this nation, and the rapidity of its development are indicated somewhat strikingly by the fact that during 1871 nearly 7,000 miles of railroad were constructed in this country—a pretty fair piece of work for one year. These new roads are distributed geographically as follows:

New England	560
Middle States	872
Southern Atlantic	422
Pacific States	170
Northern Central	992
Southern Central	170
Northwestern	3,116
Territories	225

There are now a total of over 60,000 miles of railway in this country. And it is estimated that it requires 400,000 tons of rails annually simply to keep the roads in order.

UTILITY OF SCIENTIFIC DISCOVERY.—Who can tell what a discovery may bring forth? *Cui bono?* applied, as it always is, to a new fact, is as silly as the reply of Coleridge to it was wise. Being asked *what was the use* of a particular new discovery, he retorted, "what is the use of a new born child?"

THE TELEGRAPH IN AUSTRIA.

We have received from the Director-General of the Austrian Telegraphs the following interesting particulars of the operation of the telegraph in that country for the past two years:

"The gross receipts in Austria for the year ending December 31st, 1870, was 1,858,443 florins ($929,221), and the total ordinary expenses 2,384,208 florins ($1,192,104). The extraordinary expenditures for the construction of new lines, 366,607 florins—($183,303). Deficiency, 525,765 florins ($262,882). Deficiency after adding the extraordinary expenditures, 892,372 florins ($446,136).

Number of messages transmitted during 1870, 2,264,558.

The gross receipts for the year ending December 31st, 1871, was 2,105,298 florins ($1,052,649), and the total ordinary expenses, 2,805,753 florins ($1,402,876). The extraordinary expenditures for the construction of new lines, 479,060 florins ($239,530). Deficiency, 700,455 florins ($350,227). Deficiency, after adding the extraordinary expenditures, 1,179,515 florins ($589,757).

Number of messages transmitted during the year 1871, 2,920,847.

In addition to the above-mentioned messages, meteorological reports from the stations on the Adriatic Sea were collected once a day, transmitted to the Central Meteorological Institution in Vienna, and the reports of this Institution forwarded to Paris.

The quotations of the Vienna Public Exchange were also transmitted gratis every day to all the stations of the monarchy.

The total length of their lines in the year 1871 was 2,459 Austrian miles, and the total length of their wires 7,961 Austrian miles.

The systems in operation in that country are the Morse and Hughes Letter-printing Telegraph. They employ 1,221 Morse instruments, of which 1,125 are embossing instruments and 96 ink writers, and 31 Hughes instruments. They also employ the Morse instruments as repeaters."

TELEGRAPHIC COMMUNICATION WITH AUSTRALIA.

A telegraphic cable has been successfully laid between England and Australia, although as yet there are some four hundred miles of wire to be stretched through the inland Australian wilderness, before messages can reach Melbourne. Since November, Port Darwin, in North Australia, has had the ocean cable landed there, which connects it with Java, India, and the whole Western World. The line now runs from London to Gibraltar, from Gibraltar to Malta, and from Malta to Alexandria, by three lengths of cable under the sea; across the isthmus to Suez, then by cable again under the Red Sea to Aden, then by another length of cable from Aden to Bombay. The Australian message takes to land again here, and crosses India by the Government lines to Madras. At Madras, it is once more transferred to a submarine cable, and is carried to Singapore, touching at Penang. Up to this point, messages for China and Australia have followed the same route. Here they diverge, those for China being taken northward to Hong Kong, Amoy, or Shanghai, while the Australian message is transmitted by cable to Batavia and Java, where it is taken along the Dutch line to Banjoewaugee, and from thence by cable, once more under the sea, to Port Darwin. The whole of the cables forming this enormous chain, have been made and laid by the Telegraph Construction and Maintenance Company. Their contract included a coast line, which was to have been round the north side of the Australian continent, from Port Darwin to Burketown, whence lines exist to Cardwell, Rockhamton, Brisbane and Sydney, uniting with the telegraph from Sydney to Melbourne and Adelaide, and with that from Melbourne to Launceston and Hobart Town. Opinions differ as to the precise date at which the land communications will be completed. Some say June or July.

TELEGRAPHY WITHOUT INSULATION—MEANS OF CHEAPENING INTERNATIONAL COMMUNICATION.

On Wednesday last, Mr. H. Highton read a paper on this subject at the meeting of the Society of Arts. He gave an account of the experiments which he had tried, both on long lengths of naked submerged wire, and on artificial cables, and the conclusions which he drew from them. He showed by experiment that water itself is for electricity of low tension so perfect an insulator, that a long wire on a plate of copper charged with electricity of low tension, will retain the charge even for hours; indeed, quite as obstinately as the glass of a Leyden jar retains a charge of high tension. The instrument he proposed to use for submarine telegraphy is a light slip of gold leaf, weighing from 1-500th to 1-2000th part of a grain, acted on by a powerful electric magnet, and with its motions optically magnified. The delicacy of this is so great, that simply looking at a thermopile will transmit a visible signal through the resistance of the Atlantic Cable, and a kiss or grasp of the hand a very strong signal. So that a modern Pyramis and Thisbe might exchange salutations not through a hole in the wall, but through the breadth of all the waves of the Atlantic. The use of this instrument gives an opportunity of using electricity of the very lowest tension, which, besides its other advantages, has a much less tendency to escape by faults in the wire. It was shown that a fault which caused the disappearance of all visible signals through Thompson's Speaking Galvanometer, with a resistance of 500 units, or about 125 miles of the Atlantic Cable, would still allow intelligible signals to be transmitted on this instrument with 10,000 units, or about 2,500 miles of resistance. The other advantages were the absence of all swing, such as there is in a needle, and an instantaneous movement, in spite of electro-static induction. Where it requires two or three seconds for the wire to accumulate sufficient charge to overcome the initial friction in any instrument where there is any friction, however slight, which he proceeds to move at intervals of seconds by jumps, the gold leaf having no friction begins to move instantaneously, and proceeds by an equable motion. Again, where increased sensitiveness is required, the only thing necessary is to increase the force of the electro-magnet at the receiving end. The conclusion the author drew from his experiments was, that instead of the hundreds of thousands of units of insulation of the present cables, it would be quite feasible to work through a cable having only a single unit of insulation; or if greater insulation were desirable, a wire might be used presenting much more resistance to the currents, such as a steel wire, possessing more strength, and cheaper than copper, and that electro-static induction being less injurious, much cheaper, with less gutta percha, cables might be used costing some fifth or sixth of the present prices, and that thus telegraphy might be made much cheaper and more available for hundreds of thousands of poor emigrants, instead of being the luxury of rich merchants, or speculators, or government officials. £50 a mile ought to provide a wire sufficient for all purposes of any required length.

ELECTRICAL POTENTIAL.

BY PROFESSOR J. D. EVERETT.

Electrical reasonings are, in many cases, greatly facilitated by employing the conception denoted by the name electrical potential. It may be defined as follows:—There is electrical force at a point in the air, if an electrified particle placed there would experience force tending to move it in virtue of electrical attraction or repulsion; there is electrical force at a point in a conductor, when electricity flows through the point, a conductor is said to be in electrical equilibrium when there is no electrical force at any part of it—in other words, when it is completely free from currents of electricity. Potential essentially depends upon forces (whether attractive or repulsive) mutually exerted upon each other by particles at a distance, and has been advantageously employed in the theories of gravitation and magnetism, as well as of electricity. We shall at present confine our attention to electrical potential. All the space in the neighborhood of electrified bodies is in a certain sense pervaded by their influence. This influence is completely specified by stating the numerical values, with proper sign, of electrical potential, at the different points of the space. Electrical potential never changes its value, per saltum, in passing from one point to the next. Moreover, if it is constant in value throughout any finite portion of a space not containing electricity, it is constant throughout the whole of this space. When electrical potential is constant throughout a given space, there is no electrical force in that space; and conversely, if there be an absence of electrical force in a given space, the potential throughout that space must be uniform. These propositions apply to the whole substance of a solid conductor, and to the whole space enclosed within the outer surface of a hollow conductor. Whenever a conductor is in electrical equilibrium, it has the same potential throughout the whole of its substance, and also through any completely inclosed hollows which it may contain. When a conductor is not in electrical equilibrium, currents set in, tending to restore equilibrium; and the direction of such currents is always from places of higher to places of lower potential. In like manner, when a small positively electrified body experiences electrical force tending to move it, the direction of this force is from higher to lower potential. When flow of electricity is compared with flow of heat, potential is the analogue of temperature. Heat flows from places of higher to places of lower temperature.

The precise direction of the force exerted upon a positively electrified particle (or upon an element of positive electricity) when brought to a place where potential has not a constant value from point to point, is the direction in which potential diminishes most rapidly. A negatively electrified particle (or an element of negative electricity) which potential increases most rapidly. We here use the words *increase* and *decrease* in the algebraical sense.

THE electric telegraph has reached Vardoe, a little town in the northeastern extremity of Norway, probably the northernmost town on the globe.

VELOCITY OF SOUND THROUGH WOOD.—The velocity of sound through different kinds of wood, varies very considerably. It travels faster in the direction of the fibre, than across it. The velocity of sound through pine, lengthwise of the grain, is 10,900 feet per second. Across the grain it is only 4,611 feet.

CORRESPONDENCE.

TRAIN DISPATCHING.

May 16, 1872.

To the Editor of the Journal of the Telegraph:

Some one, signing himself "Scat," writes in May 1st number of the JOURNAL, in regard to train orders. His first point appears to be an endeavor to raise a laugh on the "old man," and in so doing, he says: "In speaking my little piece, I desire to differ from the 'old man' *whose fifteen years experience has taught him* that in an order for trains Nos. 1 and 2 to meet at A., that the conductor of No. 2 can fall back on his dignity, or schedule, rather, and refuse to proceed until he has received a positive order giving him the right against No. 1. Me thinks I hear an audible smile amongst the old stagers." In reply to this I will say, first, "Scat" is mistaken in the way my article reads, or else he purposely misrepresents its words. I said: "I have had fifteen years' experience in railroading and telegraphing, *and this experience tells me that the safest way is the best.*" These were my words, as the JOURNAL will show. As to "Scat's" plan, I think it a very good one, and know that it has worked very well on the road which heads his letter. But I think there are better plans. In my time I worked some eight or nine months for the road he mentions, and I remember that this plan which he advocates as being perfect, failed to work so in my judgment. Both operators at points wanted were often not on hand at the same time. This caused the delay of *two* trains until operators were at their posts. I know my plan is an old one; but it is a *safe one*, and that is what I am trying to get at—the safest way to run trains under telegraph orders. Under the present system, as generally practiced, there are few schedules but what it will conflict with. Suppose "Scat" were to send his orders to two trains at same time, and in a minute or two after one train had got its orders and gone on, the fact should be demonstrated that the other train had broken down, or from some other cause could not make the point, and this point should happen to be *between* telegraph stations. The train which has gone is laid out for by its positive order; it cannot go ahead until the approaching train arrives or its order is made void. I never have yet seen or heard of a system of train orders that was *perfect*, and I think one would be very hard or impossible to arrange. No train dispatcher can tell at what moment any one or more of his trains will break down or fail to make time. These are times when a "positive order" will work the best; and again, there are times when a "time order" is most effective. I see no system that can be made uniform for all times or circumstances, and hence I think the *safest* is the *best*, and circumstances are bound to govern the system.

"OLD MAN."

ECONOMY IN LEAD PENCILS.

To the Editor of the Journal of the Telegraph:

Anything that occasions the saving of a penny is worthy of consideration. In this connection I would speak of the gutta percha pencil holder. It is well known that of the lead pencils used in telegraph offices, generally about one-third of the pencil is thrown aside after the other two-thirds are worn away. By the use of the holder referred to a pencil can be used until it is less than an inch in length, fully as well as when it is full size. The holder is simply a rubber tube shaped like a tapering wooden pen holder, with an opening in the larger end for admitting the end of the pencil. If such a simple, inexpensive article could save to the Western Union one-third or one-fourth of the pencils sent out, would it not make a very large item in a year? I have no ax to grind, nor do not know who is the manufacturer of this cheap commodity. I understand that these holders are used by the Union Pacific Railway Company.

ECONOMIC.

To the Editor of the Journal of the Telegraph:

Are managers compelled to write messages for those who are able to write themselves? Furthermore, are they expected to abbreviate messages when requested by persons handing them in? Where messages require answers, how long is it necessary for a messenger to wait for it after delivery? Must he await the convenience of the party replying, even though it takes a half an hour? Such is a frequent occurrence, to the detriment of other messages. Is Rule 58 only applicable to large cities, or does it include towns of 12,000 inhabitants?

ANSWER.

Managers are not compelled to write messages for persons who are able to write themselves, nor should they abbreviate messages when requested to do so by persons handing them in. Persons who desire to have their messages abbreviated should do it themselves. When requested to do any duty of this kind, the manager should decline in a courteous manner, and explain to the customer that they are requiring a service which the manager is not authorized to perform.

No general rule can be given as to how long a messenger should await for a reply to a message after it is delivered. It is of the utmost importance that a reply should be obtained to all messages which require them, and if the messenger should be compelled to wait 10 or 15 minutes to obtain one, it might save the transmission of one or more office messages of enquiry, and thus save to the company much more valuable time in the use of its wires than the value of the messenger's time in waiting for it.

Rule 58 is applicable to all Western Union Telegraph Offices, whether large or small.

To the Editor of the Journal of the Telegraph:

Will you please inform me how many words there are in the following message?

"DAYTON O., May 23.

"*To J. H. Reid & Co., N. Y.:*

"Best figures on oats; first half June; white and mixed. (Signed.) S. G. SMITH.

"Answer Carlisle, O."

There are 10 words in body of message. The question is, should the words "answer Carlisle, O.," coming after signature, be counted? Also, if just the word "answer" is put just after the signature, should it be counted the same as if inserted in body of message? By answering this through the JOURNAL, you will much oblige S. C. ROBINSON,

Opr. Union Depot.

ANSWER.

The words "answer Carlisle, O.," should be counted. The word "answer" placed after the signature, should also be counted. We are aware, however, that many offices do not charge for the word when in that position.

H. C. STRONG, of Baraboo, Wis., is advised to study "Pope's Modern Practice of the Electric Telegraph," and Prescott's "History, Theory and Practice of the Electric Telegraph." Both are Standard works.

NEW MARKET, Ohio, May 23, 1872.

To the Editor of the Journal of the Telegraph:

Would like answer to one or two questions, and others would perhaps be benefited at same time:

1. Is the holder of a frank entitled to receive answers D. H. to a message sent on that frank?

2. Can intermediate offices work Stearns' double transmission, as well as terminal ones?

3. Is not "can not" two words? I claim that they are, while a great many operators claim them to be one word. Have had a number of disputes with regard to it. By answering, you will greatly oblige ACCLURIO.

ANSWER.

The holder of a business frank is entitled to receive a free reply to a message sent on account of a frank. The holder of a social frank can receive a free reply by putting one or more additional stamps on the message that he sends, in accordance with the conditions named on the frank.

Stearns' Double Transmitter is not adapted for way stations.

"*Cannot*" is one word.

WAVERLY, N. Y., May 28, 1872.

To the Editor of The Journal of the Telegraph:

Having had a little controversy in regard to the words "car load," we have decided to leave it to you.

I claim that *car load* is two words. Am I right or wrong? By replying through the JOURNAL you will greatly oblige G. B.

ANSWER.

Car load should be counted two words.

DON'T LET THIS CHANCE SLIP.

To the Editor of the Journal of the Telegraph:

Will you have the kindness to announce that through John Ritchie, M. C., an effort is being made to get before the House of Representatives a bill giving to each operator, who served ninety days as operator in late war, one hundred and sixty acres public land, upon the same terms as that given to soldiers, by a recent enactment.

We can have it by simply asking for it.

Let every one contemplated in such an act at once write an individual letter to Mr. Ritchie, giving his voice for or against the measure.

Mr. Ritchie will need no further help than this.

We must be quick, or it will go over to next session. ISLAND No. 10.

INFORMATION WANTED

Of telegraph operator named ——— Moore, alias Jas. or Chas. Q Morgan. Is about five feet six inches high, weighs about 125 or 130 pounds, sandy hair, moustache, and wore when last seen here, short whiskers all over his face; eyes blueish gray; pleasant address; names given above probably assumed. He is a forger. Any information concerning this man will be thankfully received. Address Ben. S. Pillow, Box 28, Devalls Bluff, Ark.

EVERY iron rail on a north and south railroad, so far as I have been able to examine, is a perfect magnet, the north end attracting the south pole and the south end attracting the north pole of a magnetic needle. So, also, in a T rail on such a railroad, the lower flange attracts the south pole, and the upper flange the north pole of a needle.—(Dr. Richard Owen, of Indiana State University).

THE WONDERS OF THE TELEGRAPH.—A correspondent at St. Louis, Mo., gives us the particulars of the sending of telegrams from that city to Hong Kong, in China, and the return of answer, the time each way being only four hours, the message being sent and reply received both during the same day.

ELECTRICITY is developed in metallic wires by merely bending them, and the development appears to be independent of any thermic action.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JOURNAL OF THE TELEGRAPH,
Western Union Telegraph Company,
145 Broadway, New York.

NEW YORK, JUNE 1, 1872.

PROBABILITIES OF SUCCESS IN ENTERING THE TELEGRAPH BUSINESS.

It is our purpose in this article to treat upon, in a general way, the chances for success in life of a young man entering the business. Nothing is further from our intention than to say a discouraging word to the intelligent and ambitious now engaged in the business of telegraphing, nor to the many of the same character yet to enter. On the contrary, we desire, in pointing out the exact prospect before the beginner, to encourage, by both word and example, every praiseworthy effort to excel and to succeed. But regard for the truth, and a desire for the true advancement of our co-laborers, impels us to say here, that which may, perhaps, from a superficial reading, tend to depress the hopes and aspirations of many. There are probably those among us, however, who will see in our remarks that which will cause their efforts and their ambition to be directed to its proper course.

The beginner must understand from the first, that in the telegraph business there is no royal road to success; that whatever is to be acquired in skill and proficiency, is obtained only by sheer perseverance and hard work. Therefore, after this business has been decided upon, with a determination to make it a business for life, with a resolution that will combat all the difficulties which attend more or less every undertaking, the great and grand object to be held constantly in view, is to use all the available means for acquiring a practical and thorough knowledge of the business. It cannot be too deeply impressed upon the mind that application is the price to be paid for mental acquisitions, and nothing is as absurd as to expect them without it.

The first rule for rising is, that a young man *shall make common cause with his employer—that he shall entirely identify himself with his interests.*

This being properly understood, and skill and general attainment being granted, success is certain.

But what constitutes evidence of success? It may be said that promotion is the most sure evidence. To an extent, this is true, but it can not be so to all, for the positions open for preferment are but few, compared with the number of those who consider themselves qualified to fill them. No; the surest evidence of success and excellence is in the estimation and appreciation in which he is held by his employer. All cannot be promoted, but all can render themselves worthy of promotion.

So many would not be disappointed, if, in the outset, the goal of their ambition were properly placed; that the right direction be given to the mind. It should not be taken for granted that a business career is unsuccessful because promotion in position has not been arrived at.

The position of operator upon a commercial line, notably the service of the Western Union Company, is, undoubtedly, in a pecuniary point of view, and in opportunities for advancement, either within its own limits, or in the first class positions now so rapidly opening for competent men upon the great railroad systems of the country, superior to anything open to a young man in any other business. The opportunities for the cultivation of the mind, and the actual acquirement of a general practical business education, to the close observer, qualifying him for almost any position or business in life, are unsurpassed in any college in the land.

Let the beginner, from the outset, resolve not to seek promotion, but rather let promotion seek him. Let him prove his ability to fill a better position than which he holds, and the position will find him. What is true for the beginner, is also necessarily so for the experienced operator. Let them master every detail of the service, and be certain that they fully understand the placing of instruments in position, running connections, the formation and the care of batteries. Then let them take up the more difficult branch—that of the science pertaining to telegraphy; for it is in that field that the successful men of the future will be found. Earnest pursuit after success will certainly attain it, and its attainment will carry with it elevation and honor.

In this pursuit new discoveries will, from time to time, be made, which will benefit all concerned and be of interest to the whole world.

The communication of such discoveries to the JOURNAL would be gladly received; and here it is that the JOURNAL could afford the most powerful aid to the student, in securing to him, and himself alone, that meed of praise and reward which may be due to his intelligent industry. This is one part of the mission of the JOURNAL, and, in fulfilling it, the one which will afford us the greatest satisfaction.

DURING the year ending December 31st, 1871, the Western Union Telegraph Company erected 11,741 miles of wire in new construction, 2,488 miles of wire in reconstruction, and 725 miles of wire in repairs, making a total of 14,954 miles of new wire put up by this company during the past year.

They also used 934,122 insulators, 50,433 feet of cable, 204,889 cross-arms and 53 tons of spikes and nails.

AT a meeting of the Executive Committee of the Western Union Telegraph Company, held on the 4th day of May, 1872, the following resolutions were unanimously adopted:

Resolved, That in accepting the resignation of James D. Reid, Esq., the Executive Committee desire to bear testimony to the faithful service which for more than twenty years he has rendered to the telegraph system of the country. Connected with the earliest lines opened for commercial business in the United States, familiar with the development of the business, prominent in the local telegraph organizations of earlier days, and continuing in the service after their consolidation into the more harmonious and perfect system which supplanted them, he has given to the telegraph the best labor of his life. He has brought to that labor an unremitting diligence, an integrity of purpose, a purity of character, a spirit of kindness, forbearance and charity, which this Committee do not fail to appreciate, and which have deservedly obtained the esteem of his associates and the affection of his subordinates.

Resolved, That as a testimonial for faithful service, and as an equivalent for three months leave of absence, the President be and he is hereby directed to pay to Mr. Reid the sum of five hundred dollars.

A true copy from the minutes.

(Signed) G. H. MUMFORD, Sec'y.

OUR friend Miller, Train Dispatcher for the Illinois Central Railroad Company, at Amboy, Illinois, must have his "ancillary" qualities well developed. For the second time since he has filled that position, have those under his charge manifested their good will and appreciation toward him. This last in the shape of a handsome gold watch chain, accompanied by some very kind words.

ATTENTION is called to the advertisement of Bradley's Telegraph Instruments, by F. L. Pope & Co.

As the stock on hand is limited, and no more to be forthcoming, those in need of telegraph machinery, and preferring the Doctor's style, would do well to hasten their purchases.

THE little "sounders" manufactured by M. A. Buell, of Cleveland, are making him famous. Orders are pouring in upon him so rapidly, that he has had to increase his facilities for manufacture in order to keep pace with the demand.

See his advertisement in another column.

CHURCH'S MUSICAL VISITOR for May, just received, gives evidence of a very gratifying prospect of the fulfillment of every ambition of the publishers to produce a popular art journal in America. The nine pages of music in this number are particularly good. Published by JOHN CHURCH & Co., Cincinnati, O.

MR. J. W. COOMBS, for several years past connected with the *American Artisan*, has retired from that paper and disposed of his interest to Mr. Leicester Allen, The business will hereafter be conducted by Messrs. Brown & Allen, the latter gentleman assuming the editorial management, for which his extensive experience as associate editor of the *Scientific American* for some time past, and his great industry, particularly qualify him. The new firm have our best wishes.

NO COMMENT of ours can add force to the resolution adopted by the Executive Committee of the Western Union Telegraph Company, in accepting the resignation of Mr. J. D. Reid, from their service.

The Company has officially expressed their appreciation of Mr. Reid's character and services. Shall his immediate friends and associates in the service do less?

REASONS WHY ALL TELEGRAPHERS SHOULD SUSTAIN THE JOURNAL OF THE TELEGRAPH.

Because it is a first-class journal, especially adapted, in its reading matter, to the wants of those interested in its speciality.

Because it is a handsomely-printed sheet, at all times with twenty-four, and occasionally with thirty columns of interesting matter.

Because it will, from time to time, contain instructive and entertaining articles upon the science pertaining to telegraphy, from the pens of leading scientists, both in this country and in Europe.

Because its columns are open to all to ventilate abuses and to suggest reforms.

Because it is at all times willing and anxious to impart information in the line of the profession, and there is none more competent.

Because, with all these advantages, its subscription price is so low—barely meeting the cost of the paper upon which it is printed.

In a kind note from an old friend, in suggesting a course of conduct for the JOURNAL, he says:

"We would like to see more of the 'comic' side of our business in the paper. Can't you stir up some interest in that line?"

No one enjoys a joke more heartily than ourself. We would rather laugh than cry at any time; and so, doubtless, would all of our readers. Will the funny fellows consider themselves stirred up? Let no one who has a good joke in store selfishly keep the laugh all to himself; let us all laugh with him.

Our correspondent did not stop with a suggestion. He gives his mite to start the ball; a good one, too. Here it is:

"Here's a laugh: A Teuton left the following message at this office yesterday P. M., *verb. et lit.*:

"'*To Mrs.* ———.

"'NEW BRUNSWICK, N. J.

"'Done by fried I kome do moro.'

"Receiving clerk translated it for operator, and it was sent:

"'Good bye, Fred. I come to-morrow.'"

"There probably was a puzzled *vrow* in New Brunswick last night. It should have been sent:

"'Don't be afraid. I come to-morrow.'"

Here's another—

"The other day, a bright youth (a veteran operator he styles himself,) sent a key to his Superintendent for repairs. Accompanying the key was a note to the following effect: 'Please put in new *magnets*, as it won't work.'

"This veteran's application for an increase of salary is on file."

Send us some more.

Owing to a press of matter at the moment of going to press, we are compelled to omit the "Service" report for March. Also the acknowledgement of receipt of assessments by the Telegraphers' Insurance Association. Both will appear in our next.

Brain-work costs more food than hand-work. According to careful estimates and analysis of the exertions, three hours of hard study wear out the body more than a whole day of severe physical labor. Another evidence of the cost of brain-work is obtained from the fact, that though the brain is only one-fortieth the weight of the body, it receives about one-fifth of all the blood sent by the heart into the system. Brain-workers, therefore, require a more liberal supply of food, and richer food, than manual laborers.

ATLANTIC CABLE.

TARIFF AND RULES FOR ATLANTIC CABLE BUSINESS.

This order contains complete instructions concerning Atlantic Cable Business, and supersedes all previous orders relating thereto. All messages must be prepaid.

TARIFF OF RATES, PAYABLE IN GOLD, TO ALL POINTS IN GREAT BRITAIN, IRELAND AND FRANCE.

	To Great Britain and Ireland.		*To France.*
NOTE.—The 10 word minimum on business to or from Great Britain and Ireland is abolished.	FOR EACH WORD.	FOR TEN WORDS OR LESS.	FOR EACH WORD OVER TEN.
From New York City, and all points in Nova Scotia, New Brunswick and New England States	$1 00	$10 00	$1 00
From all points in New York (except New York City), New Jersey, Pennsylvania, Delaware, Maryland and District of Columbia	1 03	10 30	1 03
From all points in Virginia, West Virginia, North Carolina, South Carolina, Georgia, Alabama, Mississippi, Louisiana, Tennessee, Kentucky, Ohio, Indiana, Illinois, Michigan, and Wisconsin, from St. Louis, Mo., and from Western Union Co's offices in Florida	1 15	11 50	1 15
From all points in Texas, Arkansas, Missouri, (except St. Louis), Kansas, Nebraska, Iowa, Minnesota, Colorado, Dacotah, Wyoming, New Mexico, Utah, Idaho, Montana, Nevada, California and Arizona	1 30	13 00	1 30
From all points in Oregon, Washington Territory and British Columbia,	1 50	15 00	1 50

RULE 1.—*Check.*—You will state in the check:

1. The number of words in the entire message, including address, date and signature.

2. The amount charged.

RULE 2.—*Count*—The address, signature and date (if message is dated), must be included in the count and charged for.

The name of sender, and "place from," and "date," should form a part of every message, but are not absolutely required in messages to Great Britain and Ireland. Should the sender omit the "place from," it must be sent with the check. The sender is responsible for insufficient address, and corrections or alterations can be made only by a new message, which must be paid for.

The "station from" must be inserted and paid for in messages to points beyond Great Britain and Ireland.

Compound names of places, including names of Countries States, Islands, Cities, Towns, etc., and compound words, count as one word; names of individuals, firms, vessels, streets, and all other names count for as many words as they contain. The prefixes "Van," "Von," "St.," "Fitz," etc., d' or de, l', le or la, before names of *places* and *individuals*, will NOT be counted separately. In other cases they will be charged as single words.

F. O. B. and C. F. I., when written as separate letters, are each counted as three words; but when written fob, cfi, as one word.

In ordinary messages, figures and letters *having no secret signification* are counted as follows:

Every group containing five characters or less counts as a word; beyond five and up to ten, two words, and so on. Any isolated figure or letter counts as a word.

Decimal points, commas, and bars of division, used in conjunction with figures or letters, in such messages, are counted each as a figure.

EXAMPLE.

"Gold, 135⅜—135⅝; Exchange, 108¼; Cotton, 34; Petroleum, 32¼," is counted as follows:

Four ordinary words, equal to.....4 words.
135⅜—135⅝, equal to 13 figures or.....3 words.
108¼, equal to 6 figures or.....2 words.
34, equal to 2 figures or.....1 word.
32¼, equal to 5 figures or.....1 word.

Total number of chargeable words, eleven.

The comma or dash separating different groups is not counted or transmitted; but commas or dashes inserted by the sender, and forming part of a group, are counted and transmitted.

The receiving clerk must ascertain whether commas and dashes belong to groups, or are used merely to separate them.

Several quotations of stocks, numbers and prices of goods, &c., cannot be combined in one group unless the message is paid for as cipher, at double rates.

Letters added to figures, to form ordinal numbers, are counted each as a figure; thus, 137th is counted as five figures, or one word.

When figures are expressed in words by the sender, each word must be counted.

Two pence, three pence, etc., up to *eleven pence*, count as one word in each case.

Words must be written in full—abbreviations will not be allowed, except such as are in ordinary use, as Co. for Company, St. for Saint.

Underlines—When words are underlined, each underline counts as one word.

RULE 3.—*Messages beyond Telegraph Lines.*—Messages destined for places beyond the Lines of Telegraph must contain instructions from the sender, as to the places from which they are to be posted. Such instructions must be inserted immediately after the address, and charged for as part of the message. Thirty-seven cents, gold, must be charged extra for postage in such cases.

RULE 4.—*Prepaid Replies.*—The sender of a message may prepay the reply as follows: The sender must insert, immediately after the address, and pay therefor, the words "Reply—— words, paid." The number of words paid for will be written in the blank space. In cases where more than one reply is required and prepaid, the sender must state the number of replies thus: "Three replies, each —— words, paid."

Should the reply contain more words than the number specified and paid for, the sender of the reply must pay for it as a new message, at regular rates; and in such cases the amount deposited for the reply by the sender of the original message will be refunded to him, if it is ascertained on investigation at headquarters, that the reply is fully paid for by the sender thereof.

Should the reply be presented later than eight days after arrival of original, it must be treated and paid for as a fresh dispatch.

Amounts deposited to prepay replies must be entered in account, and remitted as a part of the tariff upon the original message; and must not, under any circumstances, be refunded without instructions from headquarters.

Messages to which a reply is prepaid, must not only contain the words, "Reply, —— words, paid," as a part of the message, but *must show in the check* the amount thus prepaid. For example: A message of ten words, from Virginia to London, to which a ten word reply is prepaid, must be checked thus: "10 paid, $11.50, and $11.50 for reply."

Replies which have been prepaid, must be checked in the following manner: "10 collect, $11.50—prepaid reply to No. —— of 28th."

RULE 5.—*Repeated Messages.*—In order to more effectually secure accuracy in transmission, messages may be repeated back from the station at which they have been received, to the station from which they were originally sent. Repeated messages are charged double the ordinary rates. The words "Repetition paid," must be inserted immediately after the address, and charged for.

Should the RECEIVER of an ordinary message require it to be repeated, on account of supposed error, the application for repetition must be addressed to the sending station. Such application and repetition must be treated as two distinct messages, and be prepaid by the applicant. Should an error be discovered, the charges for the application and repetition will be returned.

RULE 6.—*Code Messages*—by which are meant messages constructed, for purposes of secrecy, of disjointed sentences, or words rendering the meaning unintelligible—will be transmitted with every possible care; but the telegraph companies, while willing to investigate by post complaints, respecting errors in such messages, will not return the charges upon them, unless they be "Repeated messages." (See rule 5).

RULE 7.—*Cypher Messages*—by which are meant messages consisting of letters, grouped or otherwise, not forming any known or dictionary words, or of numerals, are counted thus: Add together all the characters, figures, letters and signs employed in the cypher text; divide the total by five, and charge each five and fractional remainder as a word. To the number of words thus obtained, add the address, signature, and any ordinary words contained in the message. CHARGE DOUBLE the ordinary rates for these messages.

RULE 8.—*Government Messages.*—American, English and French Government messages will be charged half rates between New York and Great Britain or France; that is—messages in plain language, will be charged half ordinary public rates, and messages in cypher, half cypher rates. Beyond New York and beyond Great Britain and France, full rates must be charged.

Messages of other Governments will be charged full rates.

RULE 9.—*Characters.*—Note the following characters, used by the Cable Companies:

For a horizontal dash, ——— - - - - ———

For a perpendicular dash, - - ——— ———

RULE 10.—*Complaints.*—All complaints respecting irregularity in transmission or delivery of messages, must be made by the sender, in writing. In cases of delay or error, the complaint must be accompanied by the receiver's copy of the message. In cases of non-delivery, a statement in writing from the person to whom the message was addressed, to the effect that the message has not been received, must be furnished with the complaint.

Managers are specially instructed that all claims for refunding

Digitized by Google

of tolls on cable messages, must be forwarded to the Secretary, at New York, with statement of complaint, as above. The tolls will in no case be refunded, without instructions from headquarters.

The following notice is appended to the Tariff Sheet of the Anglo-American Telegraph Company (limited):

NOTICE.—The public are informed that the Anglo-American Telegraph Company (limited) will not incur or accept any liability whatsoever, either for the due transmission of telegrams to the cable, or for their safe delivery at their destination; nor will they except any liability arising from delay or stoppage, by reason of any accident to the cable or instruments. The Company will not consent to be liable, under any circumstances, for any sum whatever, as damages or otherwise, for loss resulting from errors, mistakes, delays or other causes, in respect to any message intrusted to them, beyond the return of that portion of the charge accruing to the Company, out of the amount received, and then only in case the message should fail in transmission, when in the hands of the Anglo-American Telegraph Company (limited).

TARIFF TO PLACES BEYOND GREAT BRITAIN AND IRELAND, AND FRANCE.

On messages going beyond Great Britain, Ireland and France, charge the following rates, in gold, IN ADDITION TO THE TARIFF TO FRANCE:

For Twenty words or less.

To	ORDINARY CONTINENTAL RATES	RATE *via* FALMOUTH.
Aden	$15 00	$15 00

Turkey in Asia, Inland	3 88	6 12
Wurtemburg and Hohenzollern	1 50	4 12

For each ten, or fraction of ten words above twenty, charge, in addition, one half of above rates.

Charge the "Ordinary Continental Rate," unless specially instructed by the sender to transmit "*via* Falmouth."

Postage from any point 37 cents extra.

The words "*via* Falmouth," "*via* Russia," and "*via* Teheran," will be charged for only to London; but other instructions, as "*via* Corfu," will be charged to entire distance.

Messages for points in Japan, other than Nagasaki, must be addressed, "Post Nagasaki." (No postage.)

Messages for China and Japan will be forwarded by Falmouth or Russian lines, unless specially directed *via* Teheran or *via* Turkey. In the former case the Teheran rate, and in the latter the "ordinary continental rate" will be charged.

RULES.

(THESE RULES GOVERN THE ADDITIONAL CHARGE BEYOND FRANCE).

All compound names, including names of Countries, States, etc., and compound words, count for as many words as they contain.

Two pence, three pence, etc., count as two words in each case.

The Continental Telegraph Companies will not entertain or investigate complaints of error or delay in *unrepeated* messages.

The "Station from" must in all cases be inserted and *paid for* in messages for points beyond Great Britain and Ireland.

Messages for India and beyond require signature.

In all other respects the rules for business with Great Britain will be observed.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
June 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since May 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

140 Armstrong Run, Pa., re-opened,
Black Hawk, Col., tariff same as Central City, Col.,
201 Brownhelm, O.,
447 Belton, Mo.,
377 Cone, Iowa,
Cloverdale, Cal., tariff same as Healdsburg, Cal.,
181 Caldwell, O.,
60 Easton, Md.,
329 Eldorado, Ill.,
211 Graytown, O.,
456 Grasshopper Falls, Ks.
66 Girardville, Pa., heretofore another line office.
348 Irving, Ill.,
490 Ledbetter, Texas,
59 Lincoln University, Pa.,
181 Macksburg, O.,
211 Martin, O.,
467 Oswego, Ks.,
409 Palestine, Mo.,
480 Palestine, Texas,
85 Phenix Sta. Md.,
95 Quantico, Va.,
60 Ridgely, Md.,
260 Saugatuck, Mich.,
478 So Canadian, Ind. Terr.,
43 Tuckerton, N.J.,
181 Whipple Run, O.,
270 Warrens, Ind.,
* Yosemite Valley, Cal., re opened.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.		*Leaves this Line.*
Yosemite Valley, Cal.	50	5	Sonora, Cal., check San Francisco, Cal.

OFFICES CLOSED.

Acquia Creek, Va., Dublin, Va., Highland, Texas, Opdyke, Ill., and Rankin, Mo.

GENERAL INFORMATION.

The attention of managers of all *except "Offices having Special Sheet A"* is called to the fact that half rate messages *should not* be taken for or received from offices of the N. W. Telegraph Co.

Offices having "Special Sheet A" will take half rate messages as directed in order of February 20, 1870 which provides that half rate messages shall be taken for and received from, La Crosse, Wis, Winona, Minn., Wabasha, Minn., Lake City, Minn., Reed's Landing, Minn., Hastings, Minn., Red Wing, Minn., Stillwater, Minn, St. Paul, Minn., Minneapolis, Minn., St. Anthony, Minn., and Prescott, Wis.

Shelby Iron Works, Ala., new office in last JOURNAL, with "Tariff for Other Lines," 50 and 5 Columbia, Ala., should read 50 and 5 Columbiana, Ala.

Hereafter the "Tariff for Other Lines" from Salt Lake, Utah, to Bullionville and Pioche, Nevada, will be 150 and 15.

The name of the office heretofore known as Huron, Mich., has been changed to Rockwood, Mich., and that of Berlin, O., changed to Ceylon, O.

OFFICES HAVING "SPECIAL SHEET A"

Will hereafter check Staunton, Va., 15 cents more than "special rate" to Charlottesville, Va., and Somerville, Mass., 15 cents more than "special rate" to Boston, Mass., and Girardville, Pa. same as "special rate" to Pottsville, Pa., present rates not to be increased.

WILLIAM ORTON, Pres't.

TRANSFER SERVICE.

EXECUTIVE OFFICE
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, May 27, 1872.

On and after June 10th, *Whitehall, N. Y.*, will be added to the list of Money Order Offices.

J. C. HENDERSON, Transfer Agent.

G. H. MUMFORD, Vice-Prest.

BORN.

RIDER.—May 9, 1872, to E. Rider, Manager W. U. Telegraph Office, Meriden, Conn., a daughter.

MANNING.—May 11, 1872, to William A. Manning, of the W. U. Telegraph Office, Cleveland, O., a son.

TRAXLER.—May 21, 1872, to D. H. Traxler, Operator W. U. Telegraph Office, Wilmington, N. C., a daughter.

MARRIED.

WENTWORTH—READ.—At Malden, Bureau Co., Ill., April 24, 1872, by Rev. J. D. Baker, James P. Wentworth to Miss Mary Read.

CHRISTY—GREEN.—At Jamesville, N. Y., May 2, 1872, by Rev. J. W. Watson, Charles H. Christy, Manager W. U. Telegraph Office, to Miss Augusta E. Green. Both of Jamesville.

HOWIE—JACK.—At Detroit, Mich., May 2, 1872, by Rev. Mr. Milligan, D. M. Howie, Manager W. U. Telegraph Office at Pewamo, Mich., to Miss E. T. Jack, of Hamilton, Ont. No cards.

MOORE—WARD.—On Tuesday, May 7, 1872, at St. Marks Episcopal Church, New Milford, Pa., by Rev. J. A. Jerome, L. E. C. Moore, Manager W. U. Telegraph Office, Wilkesbarre, Pa., to Miss F. M. Ward, of New Milford, Pa.

OWEN—WOOD.—May 8, 1872, at St. Marks Church, Brunswick, Ga., by the Rev. Thomas J. Stanley, of Savannah, Ga., Mr. D. G. Owen, Manager W. U. Telegraph, to Miss Katie J. Wood. Both of Brunswick.

MARSH—MCELHANEY.—May 16, 1872, at Pittsburgh, Pa., by Rev. Mr. Johnson, Mr. Francis Marsh, Manager W. U. Telegraph Office, McDonalds, Pa., to Miss Lizzie McElhaney, of McDonalds. No cards.

TRANTWINE—SMITH.—On Thursday, May 23, 1872, in the First Moravian Church, Philadelphia, John C. Trantwine, Jr., Operator for Morris, Wheeler & Co., to Lucy L. Smith, formerly Manager of Lebanon, Pa., Office.

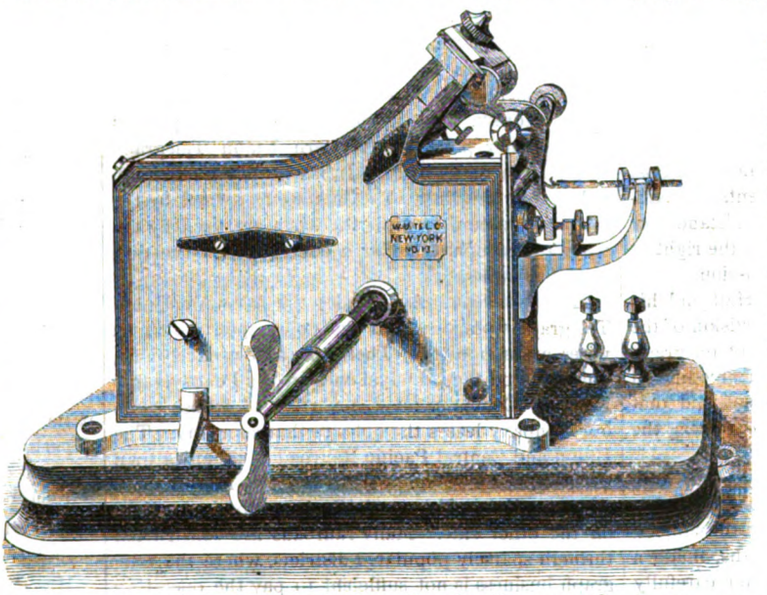
JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 14. NEW YORK, JUNE 15, 1872. WHOLE NO. 111.



NEW SPRING REGISTER.

The accompanying cut illustrates the new Morse Main Spring Register, designed by Mr. G. M. Phelps, and adopted as the standard recording instrument by the Western Union Telegraph Company.

The wheel work is entirely enclosed by the combined glass and brass frame, and the pivot holes are also covered so as to keep the instrument entirely free from dust. An extra wooden roller is attached for greater convenience of starting the paper. The paper has simply to be inserted between the wooden roller, and the guide over it, and pressed forward while the register is in motion, when it will feed through without difficulty. The rate of speed may be varied by removing the glass at the end of the case, and turning the screw under the governor.

It is not designed that the operators should take out the pen lever. When the pen requires adjustment it should be turned up or down by its milled head.

When the instruments are sent out from the factory, they are oiled, adjusted, and ready for use, and are consequently admirably adapted for operators of limited experience, who are obliged to use paper for receiving.

A NEW AND SIMPLE CONTINUOUS BATTERY.

Professor Bottomley, of the Glasgow University, thus describes a new battery in use in that institution:

A shallow wooden tray, square and with slightly slanting sides, is lined with sheet lead; and this, after being electro-typed with copper, forms both the containing vessel for the liquids and the copper plate of the cell. Copper trays were used at first, but they were soon eaten through by the solution. The lead is not attacked at all. The length of a side of the lead tray is 21 inches, and its depth is 3¾ inches. In each corner is set a small block of wood 1¼ inches high. The zinc plate, which is like a square gridiron, rests at its corners on these blocks. The zinc has parchment paper tied round its lower surface and sides. The cell is filled up with saturated solution of sulphate of zinc, and crystals of sulphate of copper are dropped in, when required, round the edges outside the parchment paper. For connecting these cells together in series, the lead lining is carried over the wooden tray at the corners and down the outside to the under surface of the bottom of it. Here it is soldered to a small square of thick sheet tin. The cells are piled up one on the top of the other, the tin plates of the second cell resting on the first, and so on. The tin connections—a suggestion of Mr. Varley—are most excellent. The resistance of each of these cells is on an average 0·19 of an ohm. They are now used at all the telegraph stations where Sir William Thomson's siphon recorder is employed.

In using these batteries in a laboratory, where they are not perpetually at work, the best way of managing them may possibly be not to charge them with sulphate of copper except when they are about to be used, and only to put in as much as will do the work required. To calculate the quantity is easy; and any small excess might be worked off through a low resistance. We have been keeping them at work almost night and day. They require no attention except to be occasionally supplied with sulphate of copper crystals, and to have the sulphate of zinc that creeps up over their edges wiped away with a cloth.

At present our battery is tested very frequently, generally once in four or five days. The electromotive force and the internal resistance of each cell is determined. We have now had the greater number of the eighty cells in action for three months, and some of them for five or six months. During all that time they have been most satisfactory, the electromotive force of them having remained perfectly constant.

SECONDARY BATTERIES.

It is well known how the Leyden jar discharges, in one strong spark, the sum of electricity it received from the electric machine. M. Planté connects a somewhat analageous apparatus with the voltaic pile. Two plates of lead (20in. long by 8in. wide) are rolled up in spiral, being separated from each other by a few strips of india rubber. This spiral is placed in a jar containing acidulated water, and having a gutta percha cover, on which are fitted binding screws connected with the plates. Twenty such elements are placed in two rows of ten each, and charged from the primary battery, which consists of two Bunsen couples. By means of a commutator of peculiar construction, these secondary elements may be connected either for quantity or for intensity. When the elements are joined in series, an electromotive force equal to thirty Bunsens is obtained, giving a current by means of which platinum wire may be fused.

In the secondary couples, the chemical action generating the current is the reaction of hydrogen on peroxide of lead, the current from the primary pile, having caused decomposition of the water, oxidizing one of the plates and developing hydrogen on the other.

By the above arrangement, the quantity of electric work from the direct action of the primary pile is transformed by condensation. This case is somewhat similar to that of a hydraulic press or crane. In a pile driver—*e.g.*, a heavy body, raised by degrees to a great height by a series of successive efforts, is then left to itself, and gives back at once the greater part of the work thus expended on it. So, when, after charging, the secondary circuit is closed, the sum of the accumulated chemical actions caused by the primary current is given out in the form of a very intense current of short duration. The effect, when the couples are joined for quantity, corresponds to the fall of a very heavy mass raised a small height; when joined for intensity, to the fall of a small mass raised to a great height. It is not difficult to see how these secondary piles may become of important use.

POSTAL TELEGRAPH.

Statement of MR. GEORGE B. PRESCOTT, *Electrician of the Western Union Telegraph Company, before the House Committee on Appropriations at Washington, April 23, 1872.*

MR. CHAIRMAN AND GENTLEMEN OF THE COMMITTEE: During the past six years various schemes have been devised for uniting the postal and telegraph systems of the United States. The first measure of this kind was proposed in the first session of the Thirty-ninth Congress, in 1865, by Hon. B. Gratz Brown, Senator from Missouri, who advocated the construction of Government telegraph lines, to be worked in connection with the Post Office, for the transmission of messages throughout the United States at a uniform rate of 3 cents per message. The result of Mr. Brown's efforts was the adoption of a resolution by the Senate calling upon the Postmaster General for information as to the expediency of making the telegraph a part of the postal system.

On the 2d of June, 1866, Hon. W. Dennison, the Postmaster General, after conferring with the various telegraph companies and experts in the United States, and ascertaining all the facts which he considered

Digitized by Google

necessary to enable him to form an intelligent judgment upon the matter, made a report to the President of the Senate, of which the following was the concluding sentence: "As the result of my investigation under the resolution of the Senate, I am of the opinion that it will not be wise for the Government to inaugurate the proposed system of telegraphs as a part of the postal service, not only because of its doubtful financial success, but also its questionable feasibility under our political system."

No further efforts were made to secure the establishment of a governmental system of telegraphy in this country until 1868, when Hon. E. B. Washburne, Representative from Illinois, in the second session of the Fortieth Congress, introduced a bill for the construction of a governmental telegraph line, under the direction of the Post Office Department, between New York and Washington, to be operated, as far as practicable) by the employés of the Post Office, for the transmission of messages at 1 cent per word, exclusive of date, address, and signature, in addition to 3 cents for postage and 2 cents for delivery.

In the same session of Congress two other bills for the construction and operation of postal telegraphs were also introduced. One of these provided that Congress should grant to Mr. Gardiner G. Hubbard and his associates, an act of incorporation, under the name of the United States Postal Telegraph Company, and confer upon it the right to construct, maintain, and operate lines of telegraph over all post-roads within the United States and territories, and also providing for a partnership arrangement between the United States and the Postal Telegraph Company, by contract with the Post Office Department, under which the company was to be furnished with office-room, stationery, lights, and fuel, and to some extent with clerks, operators, and superintendents, at the cost of that Department, and in return for these advantages the company was to send messages at the rate of 25 cents, (of which the Post Office Department was to receive 5 cents), for distances of 500 miles, and of 50 cents for distances of one thousand miles, reserving, however, the right to charge extra rates for priority of transmission.

The third bill authorized James F. Hall and his associates, under the direction and supervision of the Postmaster General, to construct lines of telegraph between Boston and Washington upon any line of travel, and be protected in the use thereof, and that all necessary materials required for constructing the lines be imported free of duty.

These three bills were referred to the House Committee on Post Offices and Post Roads, which, after a thorough and exhaustive examination of the subject, extending over a period of nine months, made a report, in which they stated that, "after carefully examining and considering the propositions contained in all the bills and papers submitted to them, and giving much time to the hearing of parties interested for and against the several measures presented, they were of the opinion that neither of the bills ought to receive the approbation of Congress."

The full and explicit disapproval of the various postal telegraph schemes, both by the Postmaster General, in 1866, and by the unanimous report of the Post Office Committee of the House of Representatives, in 1868, was generally regarded as the probable termination of the project; but in the second session of the Forty-first Congress, December, 1869, it was again revived by Hon. C. C. Washburn, Representative from Wisconsin, as whose request the House authorized the appointment of a Select Committee on Postal Telegraph, which sat for several months listening to arguments for and against the several measures presented to them, but failed to agree upon a report. Two members of the committee, however, Messrs. Washburn and Palmer, presented reports, which were ordered to be printed and recommitted. Mr. Washburn's report strongly urged the necessity for the purchase of the existing lines, and the creation of a purely governmental telegraph, and a bill was introduced by him for securing this result.

Mr. Palmer's report advocated Mr. Hubbard's scheme, and was accompanied by his bill.

No further action was taken upon either of these bills, and the discussion of the subject of governmental intervention in the business of telegraphing was not again renewed until the present session of Congress.

Although all the facts and arguments which could be adduced in favor of the governmental acquisition, interference, or control of the telegraph have been ably presented, I think it must be conceded that they have hitherto failed to produce a conviction of the expediency of such measures in Congress, the public press, or any considerable number of private citizens.

As the subject has been so fully discussed heretofore, and now presents no new features of importance, I will not occupy your time with a restatement of the reasons why the Government should not intervene in the business of telegraphing, but invite your attention to the pamphlets which I have in my hand, containing the argument of Hon. William Orton, president of the Western Union Telegraph Company, on the bill to establish postal telegraph lines, delivered before the select committee of the United States House of Representatives in May, 1870, and to the remonstrance of the Western Union Telegraph Company against the postal telegraph bill, published February 13, 1872, as embodying the views of the company which I represent upon the subject now under consideration.

Mr. DICKEY. I would like to know what proportion of their poles the Western Union Telegraph Company actually owns. In my State the telegraph poles along the lines of railroads are owned by the railroad companies, while the wires are used by the telegraph company, under a contract with the railroad companies.

Mr. PRESCOTT. As a rule, the Western Union Telegraph Company own the poles upon which its wires are supported. There are a few exceptions, however, and the principal ones are the Pennsylvania Railroad Company, over a portion of whose route our company leases the poles of that company. The Union and Central Pacific Railroad Companies own the telegraph lines on one side of their road and the Western Union Telegraph Company own the lines on the other side. Many railroads are constructed through sparsely populated districts, where the telegraph business is not sufficient to pay the operating expenses, and in such cases the railroad companies contribute to the construction of the lines and aid in their operation, receiving as compensation a commission upon the public business which is done on them, besides doing their own business free.

The CHAIRMAN. Are half the telegraph poles owned by the railroad companies?

Mr. PRESCOTT. No, sir; only a small percentage of them. As a general rule, the poles furnished by the railroad companies are contributed to the telegraph company as an inducement for building the lines, and become the property of the latter.

The CHAIRMAN. How large a force of employés has the Western Union Telegraph Company?

Mr. PRESCOTT. It has 7,264 on its pay-rolls, but there are a good many others connected with it indirectly.

Mr. DICKEY. Is there any case where the railroad companies own the telegraph poles and where the Western Union Telegraph Company does not possess the right of way?

Mr. PRESCOTT. There are a few railroad companies which own their own telegraph lines and over whose routes the Western Union Telegraph Company does not possess the right of way, but on most of the railroads our company has secured the right of way by contract.

Mr. LINES. I would like to ask about what proportion of these contracts there is where there is any mention whatever made of the right of way as a consideration.

Mr. PRESCOTT. In all contracts the right of way is recognized and constitutes a material consideration.

Mr. DICKEY. The railroad company has got the right of way, and the telegraph pole is an incident of that right of way. The right of way must be in the railroad company?

Mr. PRESCOTT. Yes, the right of way is in the railroad company, and our company has never constructed a telegraph line upon any railroad without securing from it a right of way, except in the case of the Pacific railroads, where the right of way was conveyed to the company by act of Congress.

The CHAIRMAN. I suppose that the railroad companies have not in any case parted with that right of way, except temporarily?

Mr. PRESCOTT. The right of way is limited to the duration of the contracts, some of which are perpetual and others for a long term of years. Virtually we consider the grant of the right of way as perpetual. There is a marked difference between the relations of the telegraph and railroad companies in this country and England in this regard. In England to a considerrble extent, the railroad companies owned the telegraphs on their roads, and not only operated them for the performance of their own service, but sent and received messages for the public at rates fixed by the railroad companies.

In this country, on the contrary, the Western Union Telegraph Company, as a rule, owns and operates the telegraphs on the lines of the various railroads, and not only performs the public telegraph business but also that of the railroads. When the British government purchased the telegraph lines in the United Kingdom they had to purchase from the railroad companies their telegraph interests, and at the date of Mr. Scudamore's last report, there yet remained forty-four railroad companies in various parts of the country with whom the Post Office department had not made araangements as to the amount of compensation to be paid to them for the purchase of their telegraph interests.

Mr. DICKEY. Sometimes you have your offices together and sometimes have the same operator?

Mr. PRESCOTT. Yes; very generally. In many cases the employés of the railroad companies also act as agents of the telegraph and thus enable our company to maintain telegraph stations at places where the telegraph business would not pay the wages of an operator. Nearly all railroad telegraph operators receive and transmit public messages over the Western Union telegraph lines, the railroad companies receiving a commission upon such business. The result of this is not only to enable the Western Union Company to reduce the rates, in consequence of the saving in the expense of operating the lines by this co-operative arrangement, but also to approximate more nearly than they otherwise could to a uniform tariff of charges.

The CHAIRMAN. I wish to ask a question touching the amount of the telegraph business of this country. I have here the English report for the week ending March 23, 1872, and for the corresponding week last year. The number of messages sent in England for

Digitized by Google

the week ending March 23, 1871, was 212,472; for the corresponding week of 1872, 273,643; being an increase over last year of 61,171. If this week is a fair average they are now sending messages in England to the number of 14,230,000 per annum, which is an increase of about 750,000 messages over last year.

Mr. PRESCOTT. No single week can be selected as a fair average for the year. A variety of causes may increase the traffic of one week over another. In Mr. Scudamore's report on the reorganization of the telegraph system of the United Klngdom, he states that the total number of messages forwarded in the nine months ending December 31, 1870, was 7,563,015. He also states that the heaviest week in the nine months was the week ending 23d July, when the war panic raised the number to 234,194, and that the lightest was the week ending 31st December, when the Christmas holidays brought the number down by 35,000 below the previous week. Undoubtedly there has been a large increase in the telegraph traffic in England during the past two years, but it must be borne in mind that there have been very large expenditures and great increase of facilities. On page 84 of Mr. Scudamore's report he states that the—

Total number of instruments in use on 31st August, 1870, was	4,153
Total number of instruments before transfer	1,869
Additional number under the Post Office	2,284

On page 85 is a schedule of 50 new circuits in course of formation, regarding which Mr. Scudamore says: "Large as the system now is, it will be far larger and afford far more accommodation when the new circuits, now in course of formation, are completed." These circuits embrace all the principal towns in England, Scotland, and Ireland. In Mr. Scudamore's report to the chancellor of the exchequer, dated June 3, 1871, he says:

The new wire circuits described at page 85 of my report are on the very verge of completion, but only small portions of them are as yet earning money. When they are open throughout, our revenue will immediately and largely be increased, for there is nothing more certain in telegraphic business than this, that the trade increases with the speed of transmission. I could furnish many illustrations of this, but one will, perhaps, suffice. For a long time we had no direct communication between London and Dundee, the messages being repeated at Edinburgh. The complaints of delay were great, and the complainants generally declared that they did not send half so many messages as they should send if the speed were greater. In February last, we contrived to give London direct communication with Dundee, and in the first week, the messages were doubled, and they have since gone on increasing. I could multiply instances with ease.

Undoubtedly all of the important additional circuits, above refered to, have long since been put in operation and are the principal cause for the great increase in traffic, for, as Mr. Scudamore truly observes, "*there is nothing more certain in telegraphic business than that the trade increases with the speed of transmission*," and the speed of transmission depends upon the facilities afforded.

The CHAIRMAN. Can you make an approximate statement of the percentage of increase of telegraphic business in this country?

Mr. PRESCOTT. The percentage of increase on the Western Union Telegraph lines since 1867 has been as follows: From 1867 to 1868, 8.9 per cent.: from 1868 to 1869, 23.8 per cent.; from 1869 to 1870, 15.4 per cent.; and from 1870 to 1871, 16.2 per cent. These are for the fiscal years beginning July 1. The increase in the number of messages sent over our lines during the past six months, as compared with the corresponding time last year, was 19.7 per cent.

The CHAIRMAN. That very large increase in 1868-'69 was probably the result of the consolidation.

Mr. PRESCOTT. There was no consolidation during this period, but a considerable increase in the facilities.

Mr. HUBBARD. Was that the year that you reduced your rates?

Mr. PRESCOTT. We have reduced our rates every year since 1866, but it was not during this fiscal year, but the next, that we made our greatest reduction, when the uniform square rates and the transmission of messages by night at half rates were introduced. The increase of the business during the year when these great reductions were made was only 15.4 per cent., while for the succeeding year, when there was no very material diminution in the rates, the increase was 16.2 per cent., thus demonstrating the fact that the increase in the number of messages is due more to the increase of facilities than to the reduction of rates, for during the last year there was a far greater increase in the means for rapidly performing the service than at any former period.

The CHAIRMAN. Have you anything corresponding with those weekly reports of the English Government, showing the number of complaints where mistakes are made?

Mr. PRESCOTT. We may not have anything exactly corresponding with to it. We keep a record of all the complaints which are made to our company of mistakes or irregularities in the service.

The CHAIRMAN. This report shows these facts: They keep an account of mistakes such as, "from delay in transmission;" "non-delivery;" "inaccuracies;" "overcharge;" "messages paid for and not sent;" or "twice paid for," and all other inaccuracies.

Mr. PRESCOTT. Our record of complaints is accurately kept.

Mr. DICKEY. But you have no account of mistakes where there is no complaint?

Mr. PRESCOTT. Not as a general thing, because we have no means of knowing that a mistake has occurred unless some one makes a complaint. When errors do occur we are very glad to be informed of them, so as to enable us to prevent a recurrence.

The CHAIRMAN. Here is a statement of complaints for the week ending March 23, 1872:

Total number of complaints for the whole kingdom	225
For corresponding week last year	317

I have been receiving these reports during the summer, and it has been a very curious thing to me to see how slowly but steadily the complaints have been decreasing.

Mr. PRESCOTT. The English government is managing the telegraph with a great deal of ability and success, and is improving the service very rapidly. Nearly all the skilled employés of the old companies are retained under the government, and there is no reason why, with unlimited resources in skilled labor and money, the system should not be equal to any in the world.

The CHAIRMAN. It indicates to me that during the past year they have very greatly bettered the postal-telegraph service, and it seems very remarkable to me that a thing done by the government should have so much efficiency, on the general principal that I believe private companies, or individuals, do work much better than a government can. It seems to indicate that the government in England is doing the work with remarkable accuracy.

Mr. PRESCOTT. That is true; but yet those statements do not afford conclusive proof that the number of errors is decreasing. Any person who suffers from a mistake made on our lines can obtain redress from us, or, if not satisffed with our treatment of his demands, can seek redress through the courts, and we are obliged to pay whatever damage is awarded. But if a mistake is made by Post Office telegraph in England the postmaster may refund the shilling paid for sending the telegram, but beyond this the complainant has no redress whatever, and no man has any redress under any government telegraph system. Now I cannot say what proportion of the English people would prefer a formal complaint for a shilling, but I am very confident that there is a very small proportion of the people who use the telegraph in this country who would take that trouble for so small a sum. While, therefore, the number of complaints reported by the Post Office department may approximately represent the number of errors made by the telegraph and show the ratio of improvement, it cannot be regarded as showing the maximum number. The complaints for errors and failures to deliver messages, in which damages have been claimed from our company during the past year, have amounted to only five hundred, or about ten per week.

Mr. PALMER. How much in amount has the Western Union Telegraph Company ever paid in the way of grievances? Can you give a general estimate of the aggregate amount?

Mr. PRESCOTT. During the past five years our company has paid $70,747.77, being an average of $14,149.55 per annum

Mr. DICKEY. I have brought several suits myself against the Western Union Telegraph Company.

The CHAIRMAN. (To Mr. Prescott.) Do you think that the Western Union Telegraph Company would be willing to take Mr. Hubbard's postal plan and execute it themselves?

Mr. PRESCOTT. I do not think the Western Union Telegraph Company would be willing to pay Mr. Hubbard the million dollars provided in the bill for organizing his company merely for the purpose of engaging in a business which they are already successfully performing; but with a few immaterial alterations in the bill I think our company would be willing to undertake the transmission of messages at the rates proposed by him.

Mr. Lines stated that the chancellor of the exchequer was very well satified with the price paid for the English telegraph lines. Now I have here Mr. Scudamore's report made to the chancellor of the exchequer on the 12th of July, 1871, in which he states that they had already paid for the British telegraph lines £7,518,955 for the plant. That would amount to nearly $40,000,000 for about as many miles of wire and only one-third as many miles of line as the Western Union Telegraph Company alone possesses, and yet Mr. Lines says he thinks $12,000,000 would buy all the telegraph lines in America.

Mr. LINES. That is admitting that the United States Government stand in the same relation to the telegraph companies. But I propose to show that they do not. What I read from Hansard was what the chancellor of the exchequer stated before it was ascertained how much money would have to be paid. It was when he supposed that twenty years' purchase would amount to £2,200,000.

Mr. PRESCOTT. Has there been official complaint since then that the British government paid too much?

Mr. LINES. I have read a pretty strong opinion of that sort from a member of Parliament.

Mr. PRESCOTT. You stated also that this was the only country where the telegraph lines were not under government control. Do you think that this is a true statement? Are not the telegraph lines in the Dominion of Canada, Newfoundland, and in some parts of Europe still under private control? Are not

Digitized by Google

all the principal submarine telegraph lines in all parts of the world and owned and operated by private companies? If you were to send a message to-day from any part of America to China, Japan, or Australia, it would pass over the lines of private telegraph companies throughout the entire route, with a single exception of the line from Bombay to Madras. There is more private capital invested in telegraphs to-day throughout the world than there is governmental.

Mr. LINES. I do not know how to answer that unless Mr. Prescott produces some statistics.

Mr. PRESCOTT. I have the statistics here, and they are all open to your inspection.

Mr. DICKEY. I do not know that we have got the actual capital of the Western Union Telegraph Company. Will Mr. Prescott please state it?

Mr. PRESCOTT. The capital is about $41,000,000.

Mr. DICKEY. We had Mr. Orton's statement that the net profits of the company were about 30 per cent. of the gross receipts. How much are the gross receipts of the company?

Mr. PRESCOTT. The gross receipts of the company for the fiscal year ending June 30, 1867, were £6,568,925; for 1868, $7,004,560; for 1869, $7,316,918; for 1870, after we had made a great reduction in the day-rates and introduced the night system of half-rates, $7,138,737; and for 1871, $7,637,448. The net revenue for 1867, after paying the working expenses——

Mr. DICKEY. It does not include anything for construction?

Mr. PRESCOTT. It includes nothing for construction, nor for any other purpose than the operation and maintenance of our lines. The net receipts for 1867 were $2,624,919; 1868, $2,641,710; 1869, $2,748,801; and for 1870, after the great reduction in the rates and the introduction of the night half-rate system, $2,227,965. Here was a loss in the net revenue of over half a million dollars in a single year, while, if the rates had not been reduced, the natural increase of the business would have increased the net revenue by at least $200,000. The net receipts for 1871 were $2,532,661, being a decrease from 1869, before the great reductions in the tariff, of $216,140, and a decrease from 1866-'67 of $92,258.

Now, during this time we nearly doubled the number of messages sent over our lines, and, in order to satisfactorily handle this great increase in the traffic we were obliged to add very largely to our plant, as will be seen by a statement of the number of miles of wire annually owned by the company. In 1866 we had 75,686 miles; in 1867, 85,291; in 1868, 97,594; in 1869, 104,584; in 1870, 112,191; in 1871, 121,151. Thus, from 1866 to 1871, there was an increase of 45,465 miles of wire, or about 60 per cent. We have also during this period expended about $2,000,000 in the reconstruction of our lines, so as to greatly increase their working capacity.

Mr. DICKEY. Is there anything that will show how much of that was an extension of your business, and how much of it was absorption of rival lines over the same routes?

Mr. PRESCOTT. The only absorptions by our company during this period were the Caton lines, in Illinois, and a line between Washington and New York, which was sold at auction to pay the debts incurred in working it, and which came under our control last year.

Mr. CLARK. What line was that?

Mr. PRESCOTT. The Bankers and Brokers'. Those are the only lines of importance which came into our possession by lease or purchase during that time.

Mr. HUBBARD. And the California lines?

Mr. PRESCOTT. The California lines came in previously.

Mr. CLARK. And the lines of the American and United States companies?

Mr. PRESCOTT. They were consolidated with the Western Union Telegraph Company in 1866, and are included in the statement already given for that year. During the past six years we have put up over 60,000 miles of new wire, which is a quarter more than the increase in our wires shown by my recent statement, notwithstanding the absorption of the Bankers and Brokers' and Caton lines. Every year we are compelled to replace a considerable amount of wire which has become worn out.

Mr. DICKEY. That is repair?

Mr. PRESCOTT. Yes, that is repair, although it is generally termed reconstruction. That reminds me that Mr. Scudamore places this kind of repair to construction account. In his report, dated July 12, 1871, he says:

The analysis of our accounts for the fourteen months ending the 31st March last, is not sufficiently advanced to enable us to state positively the exact proportions in which the total sum expended should be distributed between capital and revenue. Throughout the fourteen months, we have constantly had large gangs of men engaged, at one and the same time, in putting in order the property which we have bought and in constructing fresh lines, (the cost of which, two operations is properly chargeable to capital,) and in ordinary maintenance work, such as the repairs of casual damage, the taking off of faults, and other work of the kind, the cost of which is properly chargeable to working expenses. We could not avoid this in the first year of our work; but our reconstructions are now nearly complete, and when our present scheme of constructions, which are also approaching completion, is finished, further constructions will no doubt be provided for by annual vote.

Mr. Scudamore has apparently yet to learn that reconstruction, like construction, is something which is never finished. A telegraph line is scarcely built before decay begins; and its reconstruction is as necessary an item to be considered and provided for as the ordinary working expenses of the wire.

If the Western Union Company should charge its repairs to construction account, it would apparently increase the net revenue over three-quarters of a million of dollars annually.

The CHAIRMAN. Do you doubt the correctness of the report of the chancellor of the exchequer, that the net profits for the last year were £50,000?

Mr. PRESCOTT. I have not seen the report you allude to.

The CHAIRMAN. I refer to the statement made in a cable dispatch, given some weeks ago.

Mr. PRESCOTT. I do not question the accuracy of the report of the chancellor of the exchequer, or of any other British official; but I think, in making up their telegraph accounts, many important items which we should charge to ordinary working expenses the British post-office telegraph carries to construction account, and thus their net revenue is made to appear greater than the facts warrant. I have here Mr. Scudamore's report to the chancellor of the exchequer, dated June 3, 1871, which includes a statement made by George Chetwynd, receiver and accountant general, showing the amount of telegraph revenue collected from the commencement up to March 31, 1871, and the expenditures for the same period. The total receipts are stated at £798,580, and the total expenditures as £1,397,389. The expenditures are divided into two classes, namely, capital expenditure £926,894, working expenditure £470,495.

Under the head of capital expenditure are £346,794 for poles, arms, wires, insulators, instruments, batteries, and tools, none of which items are to be found under the head of working expenses. And yet, how could a telegraph of the magnitude of the British system be worked fourteen months without requiring a heavy necessary outlay for these articles irrespective of construction?

Under the head of capital account £377,449 are also placed for engineering salaries and traveling expenses, alteration of buildings, preliminary instruction, bonuses to learners, office-fittings, examining accounts of telegraph companies, law expenses, &c., none of which items appear under the head of working expenses, although just such expenses must continue to be made every year as long as the telegraph is maintained.

Now, I do not doubt the correctness of these figures at all, but I think a considerable portion of them would be much more properly placed under the head of working expenses than capital account. This matter of the proper division of the expenditures, however, I regard as of small importance. There is no reason why, at the rates charged, the English telegraph should not be self-sustaining ultimately, if it is not now; and there is no room for doubting the fact that it has greatly improved since it passed under the control of the government. The opening of 1,350 new offices and the erection of 30,000 or 40,000 miles of wire could not fail to vastly improve the capacity and value of the system. The plans adopted by Mr. Scudamore for carrying out the work were admirable, and evince great judgment and ability on his part. The work of reorganization and extension was intrusted to the officers of the companies which were bought out, and the position of engineer-in-chief of the post-office telegraphs was given to Mr. Culley, the former electrician of the Electric and International Telegraph Company. While I see no reason, therefore, why the British post-office telegraph system should not equal any other in the world, I do not consider its success as in any manner due to its subordination to the post-office authorities, but regard it as mainly due to the unification of the system by uniting all the lines under one control, and by the extension of its lines so as to afford prompt telegraph communication between all parts of the United Kingdom. The reduction of tolls in Great Britain since the lines were placed under control of the Government has been no greater than in this country, since October, 1869.

The tariff between London and many important places where the bulk of the business was done was a shilling before, while the rates throughout the metropolis have been raised by the government from sixpence to a shilling per message. The advantage of having a uniform rate is indisputable, and in small compact countries can be maintained without difficulty, but in a country so extensive as the United States it would be impracticable, except at rates which would be unsatisfactory to those who wished to send over short distances.

Mr. HALE. You have given your gross receipts and your net receipts; what were your dividends during those years?

Mr. PRESCOTT. The Western Union Company has not made any dividend since January, 1870. The dividends, when they were made, were two per cent. semi-annually. Occasionally the dividend was passed. The company has never paid over four per cent. since 1866.

Mr. DICKEY. I recollect when I got four per cent. a quarter.

Mr. PRESCOTT. Not for the Western Union Telegraph Company, I think. I have been a stockholder in the company for eight or nine years, and I never got any such dividend as that.

Mr. DICKEY. I don't speak of that being the dividend on the capital stock, but on the cash put in.

Mr. HALE. What is the stock selling at?

Mr. PRESCOTT. It was selling at 76 yesterday.

Digitized by Google

Mr. HALE. What was it selling at two years ago?

Mr. PRESCOTT. I think it sold from 35 to 40.

The CHAIRMAN. How is it that the prices have doubled within two years when there has been no dividend?

Mr. PRESCOTT. It is evident enough that if we make a profit of $2,500,000 per annum and, instead of paying dividends, put the earnings into new lines, the stock ought to become more valuable.

The CHAIRMAN. Not for the stockholders.

Mr. PRESCOTT. That depends upon how long the stockholder keeps his stock.

The CHAIRMAN. It may be that there will be a pretty big dividend to come. Do you know whether anything of that sort is intended?

Mr. PRESCOTT. It would not surprise me if there should be, although I do not pretend to know anything about it. As for the reasons for the fluctuations in the price of stock, you might as well ask me why Erie sold at 18 two years ago and 65 now.

The CHAIRMAN. I think that the Erie Ring and the late explosion explain that.

Mr. PRESCOTT. I bought Western Union Telegraph stock at par seven years ago and hold the same certificates now. There have been no stock dividends since, and yet the actual property value has been very greatly enhanced by the construction of new lines and the reconstruction of the old. The temporary depression of the stock two or three years ago was no criterion of its value, as the action of the present investors clearly shows.

Mr. LINES. I would like to ask Mr. Prescott whether he is perfectly satisfied that there will be no redress under the management of the Post-Office for malfeasance in any of the telegraph employees?

Mr. PRESCOTT. I do not know what sort of justice might be dealt out to the employés of the Post Office, but I am very sure that the public would have no remedy.

Mr. LINES. Cannot there be action in court for the malfeasance of a postmaster, clerk, or operator?

Mr. PRESCOTT. Suppose you send a valuable letter through the Post Office and it is stolen by one of the employés? If the fact could be proven the employé would doubtless be punished, but that would not reimburse you for your loss, and you could not get any redress from the Department.

Mr. DICKEY. Mr. Prescott is correct about that.

Mr. PRESCOTT. I do not consider it necessary at this time to criticise Mr. Hubbard's argument in favor of his bill, but I deem it proper to say that the greater portion of his remarks relating to our company are incorrect, and that there is no foundation, in fact, for any of the following statements, viz.:

1. That the rates at the West are twice as high as those at the East.

2. That the rates are higher between the principal cities now than they were six years ago.

3. That the amalgamation of the United States and the Western Union Companies raised the rates in many parts of the country, and they have never been reduced between the large cities.

4. That the Western Union Company has raised the rates so as to crush out more than one newspaper.

5. That the Western Union Company has issued notice to exclude any paper from receiving news which undertook to criticise it.

6. That within a year this company has cut off a paper for criticising reports.

7. That commercial news is sent over our lines to the exclusion of all other business, by priority.

I have already stated that the rates have been constantly reduced every year since the consolidation of the United States and American lines with the Western Union, in 1866. In no instance was that consolidation followed by an increase in the tolls. As our gross revenue for 1871 shows an increase over that of 1869 of less than 5 per cent., while our net revenue decreased in the same time over 8 per cent., how can Mr. Hubbard's statement, that we have doubled the number of messages transmitted, be reconciled with his assertion that we have only reduced our rates from 15 to 20 per cent.? Of course, if we have doubled our business and only decreased the rates 20 per cent., our gross revenue should show an increase of 60 per cent. instead of 5.

A great deal of importance has been attached to the proposition to unite the postal and telegraph systems of the country, and European experience is referred to as evidence of the benefits to accrue from such a union; but while it is true that the aerial telegraphs in continental Europe are, for the most part, owned and controlled by the governments of the respective States through which they run, the assertion that they form a part of the public postal system is erroneous. England is the only country in Europe where the telegraph and postal systems are united. In North Germany, which comprises twenty-two states, the administration of the telegraphs constitutes a distinct department under the government of the confederation, Major General De Chauvin being director general of telegraphs, assisted by ten directors, having their headquarters at Berlin, Breslau, Cologne, Dresden, Frankfort, Halle, Hamburg, Hanover, Kœnigsberg, and Stettin. The telegraphs in Austria, Hungary, Bavaria, Würtemberg, Baden, and Holland form one system under the head of the South German Telegraph Union, and in the several States are managed as distinct departments by their respective directors general. In Russia, France, and Spain, the telegraphs constitute a distinct department under the minister of the interior; in Belgium, Italy, and Portugal, under the minister of public works; in Denmark, Norway, and Sweden, under the Minister of Finance; and in Switzerland the administration of the telegraph constitutes a distinct department under the federal council. In fact, in all the continental countries of Europe the telegraph constitutes a distinct department, and, although the post office, railways, and customs, as well as private establishments, supply the elements of an auxiliary staff, all the persons employed in the transmission and delivery of the telegrams depend upon the administration of telegraphs for their compensation, and in the annual budgets appropriations are made for that service distinct from the post.

As, therefore, none of the telegraph systems in continental Europe are under the control of or are united with the Post Office departments, all considerations of value or experience based upon the theory of such a connection should be eliminated from any estimate which may be made in reference to the proposed union, in whole or in part, of the telegraph and postal systems in the United States.

The question, however, as to what department of the government the telegraph is attached is of no great importance. It is a service in every branch of which skilled labor is required, and whether it be under the control of the minister of the interior, finance, public works, or the postmaster general, it can only be successfully managed and operated by telegraphists especially educated for this peculiar service. Whether the telegraphs are as well managed in Europe under the various governments as they might be, or as they probably would be in those countries by private companies, I do not feel called upon to discuss. Neither do I regard the extent of the telegraphic facilities furnished in Europe, or the price at which messages are transmitted, as of any particular consequence in considering the comparative merits of governmental and private control of the telegraph, since the government may send messages at any tariff it chooses to establish, and furnish such facilities as it deems best, totally irrespective of the important question as regards private companies as to whether the revenue shall equal the cost of the service.

I think, however, I may very properly compare the telegraphic facilities furnished in Europe under governmental control with those in this country, where the construction and operation of the telegraphs have hitherto been left to private enterprise.

In Europe the telegraph system embraces 175,490 miles of line, 475,007 miles of wire, 21,146 sets of instruments, and 15,503 offices.

In America the telegraph system embraces 85,583 miles of line, 165,875 miles of wire, 8,655 sets of instruments, and 6,755 offices.

The ratio of telegraphic facilities to population in Europe is as follows:

Number of inhabitants to each mile of line	1,744
Number of inhabitants to each mile of wire	642
Number of inhabitants to each office	19,687
Number of inhabitants to each message sent	9½

The ratio of telegraphic facilities to population in America is as follows:

Number of inhabitants to each mile of line	486
Number of inhabitants to each mile of wire	250
Number of inhabitants to each office	6,161
Number of inhabitants to each message sent	$2\frac{25}{100}$

It will thus be seen that, as regards the facilities furnished in proportion to population, America is far in advance of Europe.

The tolls for the transmission of messages are not the same for any two countries in Europe, nor are they uniform for all classes of messages in any one country. Telegraphic correspondence in Europe is divided into two general classes, called internal and international messages. The internal messages are those which are received, transmitted, and delivered in the same country; the international messages are those which are received in one country and transmitted into another. As a general rule, a low rate of charges is adopted for the transmission of internal messages, while a higher tariff is imposed upon international messages.

The telegraphic tolls in continental Europe in 1869 averaged 36 cents for internal messages, and $1.01 for international messages, which is a higher average charge than is imposed in this country, although it is well known that skilled labor is much more expensive here than in Europe.

The Western Union Telegraph Company has for the past six years been successfully striving by the improvement of its lines and machinery and by the employment of the most skillful operators, to secure the most prompt and satisfactory telegraph service in the world, and I believe the results will show upon investigation that it has fully succeeded.

The claim that the Western Union Telegraph Company is now, or may hereafter become, a dangerous monopoly is entitled to no consideration whatever, since, in the first place, the telegraph business is everywhere in this country open to free competition, no one company having any advantage over another, except what it legitimately acquires by the greater skill with which it performs the service; and, in the second place, the act of 1866, which constitutes a compact between the Government and the Western Union Telegraph Company, provides that the United States may at any time, after the expiration of five years from the date of the passage of the act, purchase all the telegraph lines, property, and effects of the company at an appraised value, to be ascertained by competent disinterested persons, two of whom shall be appointed by the Postmaster General of the United States, two by the company, and one by the four so previously selected.

In conclusion, permit me to say that as the success of Mr. Hubbard's scheme would inevitably depreciate the value of the property of this company, which the Government can at any time take at an appraisal, not of its cost but of its value, I submit that Congress cannot consistently and in good faith confer such a franchise upon Mr. Hubbard without first releasing this company from the obligations of the above act, and providing a just measure of compensation for the depreciation of its property which would result from the granting of such extraordinary privileges to a competitor.

JOURNAL OF THE TELEGRAPH.

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, JUNE 15, 1872.

JAMES GORDON BENNETT *VERSUS* THE TELEGRAPH.

In editorially announcing the recent death of its founder and proprietor, JAMES GORDON BENNETT, the New York *Herald* says: "He was ever ready to give his earnest and powerful aid to the establishment of Steamship Lines, Railroads, and Telegraphs, which he recognized as the great missionaries of civilization, and the life-blood of a perfect daily newspaper."

As to the late Mr. BENNETT having been a patron in the establishment of Steamship Lines and Railroads, we have no knowledge, and therefore will raise no question. But as to his merits as a promoter in the establishment of the TELEGRAPH, we propose to submit the following well known incident, which will enable our readers to judge with reasonable certainty:

It will be remembered that the first line of Telegraph established in the United States, was the experimental line between Washington and Baltimore, for which the means was furnished by Congressional appropriation out of the public treasury, which was completed in the spring of 1844. Farther Government patronage was prevented by the advice of the Postmaster General, who, in his report to Congress, declared his belief that the Telegraph, although an interesting experiment, could never become of practical value, and the very moderate offer of Prof. MORSE for the sale of his entire invention to the United States Government, was declined.

The only resource for its future development, was in an appeal to the enterprise of the business men of the country. In order to bring the invention to the attention of the business interests, Mr. EZRA CORNELL, (one of the founders, and still a director of the present WESTERN UNION TELEGRAPH CO.,) who had superintended the erection of the Washington and Baltimore line, opened for exhibition a short line of Telegraph in Boston. Finding but little encouragement in that city, the exhibition was soon abandoned there, and transferred to the city of New York, where an experimental line was opened in the autumn of 1844, for exhibition to the public. The line extended from 112 Broadway to a point just above the present Metropolitan Hotel. So little attention did this wonderful invention then receive, even at the modest admission fee of one shilling per head, that Mr. CORNELL and his assistant found it extremely difficult to maintain themselves in the most humble manner, upon the entire receipts of their exhibition. Sleeping upon the chairs in their exhibition room, they often found it necessary to go to bed supperless. Without the means of paying for advertising, the daily papers were besought to notice the exhibition editorially. Kindly notices were given by the *Express* and *Evening Post*, as well as some of the other papers of the day, but not a word could the *Herald* be induced to say. Finally Mr. CORNELL sought an interview with Mr. BENNETT, and solicited his attention. He was met by the very frank statement by Mr. B. that he was opposed to the success of the TELEGRAPH. In Mr. BENNETT's own words, he "had at great expense established his expresses in such manner that he could beat all of his rivals, and if the TELEGRAPH were once successfully established he would lose his advantage."

Within two years Mr. CORNELL had the proud satisfaction of demonstrating to Mr. BENNETT the value of his then mode of transmitting important news. During the year 1845, mainly by the efforts of THEODORE S. FAXTON and his associates of Utica, a company was organized for building a Telegraph line between New York and Buffalo. The section between New York and Albany was built under the superintendency of Mr. CORNELL, and was opened for business at the end of 1846. Governor YOUNG's annual message was transmitted to the Legislature the first Tuesday of January, 1847, at noon. At that hour a *Herald* messenger, with a copy of the message, left the Capital on horseback, provided with relays of fleet horses at short intervals. Riding at break-neck speed all night, he reached White Plains (to which point the Harlem Railroad was then in operation) the following forenoon, where a special locomotive was in waiting to bring him to the city. What was his surprise to meet at this point newsboys selling copies of the New York *Express* of that morning, containing GOVERNOR YOUNG's message in full, which had been transmitted by the despised TELEGRAPH. Thus Mr. BENNETT's enterprise was at a single blow completely annihilated, and the TELEGRAPH was successfully established in spite of his chilling indifference.

ON Thursday, June 13th, 2,155 messages were exchanged between New York and Boston. Of this number, Mr. Barrett sent with the Phelps printing instrument in seven hours 606 messages, being at the rate of over 86 messages per hour.

NOTICES of Marriages, Births and Deaths, must, if sent to us for publication, be authenticated by the name and address of the party sending them, or they will not appear.

HERE is a matter seemingly small in itself, yet involving an important issue. We give it to point out the necessity which exists for care and vigilance in the handling of business. In this case it is evident that both the sending and the receiving operators were at fault, though in different ways:

A telegram was left at the telegraph office in an eastern city, directed to "Chase, Stewart & Co.," New York. Owing to the poor manipulation of the key by the sending operator, the message was received as to "Chas. E. Stewart & Co." This, however, was not the only mishap. The operator who received the message put down the address as "C. E. Stewart & Co."

The result was that Chase, Stewart & Co. did not receive their dispatch, and it ultimately found its way to the hands of a wrong party, whose name in some degree was similar to their own.

The substitution of the initials for the full name, which in this case was undoubtedly sent, though not in a clear manner, was not a blunder. It was worse. It evinces negligence and carelessness. Such matters injure the reputation of the Company, and bring discredit upon the service.

IN another column we give a communication from "Buffalo," upon the delays to business and the extra service entailed upon the Company, arising from an unintelligent performance of duty, which is very suggestive, and worthy of general attention. Our correspondent takes a very proper view of the subject he discusses, and, doubtless, if all of those entrusted with the performance of the business of the Company evinced a like intelligence, and as just an appreciation of the proper fulfillment of their duties, the service would be greatly benefitted thereby.

In comment we would say, however, that as a general rule, operators should not take it upon themselves to alter the phraseology of a dispatch, or the spelling of a word, even if manifestly wrong; yet a wise and discriminating judgment would, if exercised, greatly aid in facilitating the transmission of such messages as are covered in the communication of our correspondent.

Many of the difficulties of this nature arise from—to place it in the mildest form—the inattention of the receiving clerk. It is the unmistakable duty of this person to be sure that he can read every word in a message tendered for transmission before he accepts it from the sender. Also, that if he perceives anything wrong in the message, to suggest in a polite manner, a correction. This can be done without giving offense, and generally to the satisfaction of the sending party. Were this done in every instance necessary, much, if not all of the trouble referred to, would be obviated.

To those sending us communications for publication, we would say: Write only upon one side of the sheet. When both sides are written upon, it causes annoyance to the printer, and some little trouble to ourself.

CORRESPONDENCE.

FOLLOWING COPY.

BUFFALO, May 28th 1872.

To the Editor of the Journal of the Telegraph:

In your issue of May 1st, a member of the profession asks for a rule governing the transmission of misspelt words, *i.e.*, "following copy." In answer to the enquiry, the editor seemed to take the ground that the only safe rule for operators to follow was to abide by the copy and send messages *verbatim*. I for one would regret very much the establishment of such a rule, and I shall hope to prove by this article that it would be the means of increasing an already incalculable amount of confusion and mischief. The majority of the messages which are now "held" for "correction," are the result of this very habit, or implied rule, of "following copy," and I feel confident that you will agree with me that there is nothing so annoying or perplexing as the numerous "corrections" which already flood our offices, and take possession of the "circuits"—a too large share of the time; and I, therefore, assume that any means should be adopted which will guard against, or remedy, this most prolific and growing evil. My experience has taught me to believe that almost invariably the error is committed in the transmission of the message from its originating office. I claim that when the sender *knows* that the writer of the message has made a mistake, and does not seek to repair the error, he commits an act of gross negligence; and yet, such cases are of frequent occurrence. In the transmission of cipher, legal, or foreign messages, it is of course indispensable to follow "copy;" but I hold it to be arrant nonsense and the height of folly to send the word "salt," "*calt*," or "Chicago," "*Shiagow*," merely because the writer, who knew no better, has not written Websterian English. To start such a message as I have mentioned is to secure a vast deal of trouble and unnecessary delay; and if the destination is somewhat distant, by the time it reaches the person to whom it is addressed the misspelt words have been underscored in some repeating office, and the mystification is complete, for, upon its reception, the party for whom it is intended does not understand the message in its then present shape, but thinks it *must* be of unusual importance as it is emphasized and asks for a repetition; whereas, the emphasis (?) has been innocently added by some "knight of the quill" in his, or her anxiety to clear their skirts of the disgrace of having perpetrated a "bull." The message consequently goes back for repetition and correction, and a host of office messages, and delay by the wholesale, naturally follows. There should be a judicious and proper regard for what is termed common sense—great care and discretion must of a necessity be exercised in the reading and transmission of messages, and many errors which now occur would be avoided. One can imagine pretty clearly with what surprise the firm of Smith & Jones read a despatch saying, "your wife left on the evening train," and particularly amusing when neither Smith nor Jones are married, while Smith T. Jones is anxiously wondering why he receives no news of his wife's intended departure. Many such and similarly stupid mistakes have occurred, and will continue to occur unless operators consider themselves something more than a mere machine!

It may be urged, "Thats the way its written;" "The clerk ought to rewrite the misspelt words;" or perhaps some may say, that my remarks do not apply to actual practice. To the first I answer, we may much better repair the error before it has assumed greater proportions, and when it can be easily corrected or prevented, rather than be obliged to correct the mistake after much trouble and delay. Second, perhaps if the clerks were engaged in re-writing they would have but little time to perform their necessary and legitimate duties. Thirdly, my remarks *do* apply, and *will* until we operators do our share (easily accomplished) toward making the application unnecessary.

The beneficial results to be achieved by a course such as I have mentioned may be summed up as follows:—There will be fewer repetitions called for, less delay, and consequently better satisfaction guaranteed to the public. Less occupation of the wires for correcting mistakes, which ought never to have occurred, thus giving additional time for the transaction of more profitable business for our employers; and, finally, it will be a source of genuine comfort to see the "hooks" clear, comparatively, of bungled and incomplete messages, which are ever an "eyesore" to those who love to see things "done decently and in order."

BUFFALO.

ANSWERS TO CORRESPONDENTS.

"DID not meet. Send by Bogley's express ten dollars ($10) to Great Falls House."

The above message contains fourteen words, Great Falls House being counted as three words.

Per cent are two words, and are counted two words.

C. A. O. is informed that Rule 17 prohibiting the receiving for transmission over the wires of this Company, messages containing profane and obscene language, should be strictly observed. No person in the employ of the company should ever receive messages of this description under any circumstances.

THE present address of Mr. Robert J. Fowler is desired. Will some one knowing of his whereabouts reply through the columns of the journal.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
June 15, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since June 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

289 Atkinson, Ind.
181 Ava, O.
47 Barnegat, N. J.
120 Crittenden, N. Y.
74 Cato, N. Y.
47 Coalport, N. J., re-opened, check Trenton, N. J.
Creswell, Or., tariff same as Albany, Or.
151 Dixmont, Pa.
30 East Berkshire, Vt.
38 Enosburg Falls, Vt.
* Eckhart, Md.
289 Earl Park, Ind.
92 Fair Haven, N. Y.
242 Florence, O.
289 Fowler, Ind.
457 Godfrey, Ks.
120 Grimesville, N. Y.
60 Greensboro, Md.
Gallatin, Cal., tariff same as Los Angeles, Cal.
66 Grand Tunnel Colliery, Pa., check Wilkesbarre, Pa.
319 Grayville, Ill.
Haywards, Cal., re-opened, tariff same as San Francisco, Cal.
38 Highgate Springs, Vt.
370 Ironton, Mo., re-opened.
237 Jonesboro, Ga.
139 Laona, N. Y.
308 Loda, Ill., re-opened.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.		Leases this Line.
Eckhart, Md.	20	1	Cumberland, Md.
Margaretville, N. Y.	40	3	Roseout, N. Y.
Ocean Mines, Md.	20	1	Cumberland, Md.

OFFICES CLOSED.

Armstrong Run, Pa., East Foxburgh, Pa., Madison, Ark., New Hope, O., Newton, Miss., Pilot Knob., Mo., Woodlawn, Ill., and West Danby, N. Y.

GENERAL INFORMATION.

The name of the office heretofore known as Townsend, O., has been changed to Collins, O.; that of Jonesboro, Ill., changed to Anna, Ill.; and that of Michigan Southern Crossing, Ill., changed to Grand Crossing, Ill.

Hereafter the "Tariff for Other Lines" to Frostburg, Mount Savage and Lonaconing, Md., will be 20 and 1 from Cumberland, Md.

The P. O. address of Weehawken, N. J., is "Weehawken, Hoboken, N. J., P. O."

Business for East St. Louis, Ill., will hereafter be checked to St. Louis, Mo.

In JOURNAL May 1, 357 Oscow, Ill., should read, 357 Osco, Ill.

The office at Seaville, N. J., will hereafter be checked direct.

CUBA CABLE BUSINESS.

We are notified of following rates to offices on West India and Panama Co.'s lines, to take effect June 1, 1872.

ATLANTIC CABLE BUSINESS.

We are notified that the "Ordinary Continental Rate" to the following countries is reduced from $1.50 to $1.00 for twenty words and under; half the latter rate for each ten or fraction of ten additional words.

Baden, Bavaria, North Germany, Wurtemburg and Hohenzollern. To take effect at once.

The following question in relation to tariffs, with its answer, should be noted by managers:

"From time to time, tariff rates to certain points have been given as follows: To A. so much more than to B. Does any subsequent change in rate to B. alter rate to A.?"

ANSWER.

No. The tariff to A. remains the same.

WILLIAM ORTON, President.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, June 10, 1872.

On and after June 20, Springfield Mass., and Memphis, Tenn will be added to the list of "Offices Specially Authorized."

I. C. HENDRICKSON, Transfer Agent.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 15. NEW YORK, JULY 1, 1872. WHOLE NO. 112.

PROPAGATION OF ELECTRICITY.

Prior to 1827, the ideas which were entertained regarding the propagation of electricity, were exceedingly vague and indefinite. In consequence of its enormous velocity of transmission, it was imagined to be analagous to light, and in the phenomena relating to the latter, indications were sought for eliminating the laws governing the former. It was not until 1827 that the truth began to appear, and to be exhibited under its true aspect. At this epoch, Ohm, a German mathematician, struck with the idea that the propagation of electricity might well be similar to that of heat, applied to it the formulas which Fourrier and Poisson had deduced respecting the latter, and promulgated in a clear and precise manner the beautiful laws governing the transmission of electric currents, which bear his name, and which experience has again and again confirmed. But to establish wholly a basis of calculations upon a parallel hypothesis, at a time when the thoughts of scientists were all turned in another direction, required to be more of a philosopher than a scientist, and that is precisely why Ohm, being a mathematician, was able to establish, without preconception and without prevention, his admirable theory. Nevertheless, his labors did not receive in the scientific world the success which should have attended them, but on the contrary, subjected him to a persecution which pursued him even in his position as professor. It was not until ten years later, and after M. Pouillet had arrived at the same laws by experiment, that the scientists began to revise the judgment which they had formed against Ohm, and to appreciate the merits of his discovery. In the meantime, although adopting the formulas of the illustrious mathematician, the scientists have refused, until within the past ten years, to admit his theory of the assimilation of the propagation of electricity to that of heat, and it is probably owing to this action on their part, that they have arrived at such discordant results regarding the velocity of the electric current.

Towards the end of the year 1859, M. Gaugain, an able electrician, who had for some time occupied himself in verifying the laws of Ohm in regard to the transmission of electricity over bad conductors, sought to solve the causes of this disaccord, and at last found the key to the enigma. He became convinced that electricity, instead of being propogated as a wave, or in a manner analagous to that of sound or light, was, on the contrary, transmitted, as stated by Ohm, in the manner of heat in a metallic bar, which is hot at one end and cold at the other. In this case the heat and the cold communicate from place to place gradually, from the two extremities of the bar, and in proportion as this double movement of heat and cold is propagated towards the middle of the bar, the parts first heated and cooled acquire and lose a quantity of heat until the two calorific movements having met each other, the different points of the bar lose on one side as much heat as they gain on the other. Then the calorific equilibrium is established, and the distribution of heat upon all parts of the bar remains the same. This is what is called the permanent calorific state. But before a metallic bar arrives at this state, it requires more or less time, according to its calorific conductivity, and this time, during which every point of the heated body unceasingly changes in temperature, constitutes a variable period, which, if the assimilation of the propagation of heat with that of electricity is true, ought to exist in the first moments of the transmission of a current; for, in this hypothesis, an electric current is only the result of the equilibrium which tends to establish itself from one extremity of the circuit to the other, between two different electric states constituted by the action of the battery, and representing, consequently, the two different temperatures of the heated bar. Without doubt, this period, variable by reason of the subtility of the electric fluid, must be exceedingly short; but for very long circuits, and for transmission over poor conductors, it would be appreciable, and that is what the experiments of M. Gaugain fully demonstrated. Since then he has investigated the laws of the transmission of the current during this variable period, and he has established, among other laws, that the necessary time for a current to obtain the permanent state in a circuit, that is to say all the strength which it is susceptible of acquiring, is proportional to the square of the length of the circuit. This result was not only forseen by Ohm, but still more, mathematically formulated by him in the equation representing the tension of the different points of the circuit in the variable period of the strength of the current. Thus Ohm, who was not a scientist, discovered by force of reasoning a phenomena, which the electricians only discovered thirty-four years later.

We shall presently show the laws of the current in the two periods of electric propagation, but it is essential that we first examine the distribution of the electricity in the circuit.

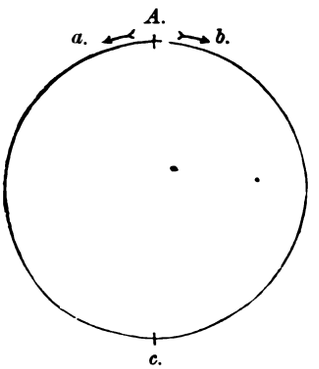

Fig. 1.

Let the ring, (figure 1), represent a homogeneous conductor, and an electric machine be supposed to exist at A. The electricity from the machine will diffuse itself over both sides of the ring; the positive passing toward *a*, and the negative towards *b*, both fluids uniting at *c*. Now, if the electricity be so distributed over the ring that a heaping up of the fluid nowhere occurs, it follows that equal quantities of electricity will pass through all cross sections of the ring in the same space of time. If it be assumed that the passage of the fluid from one cross section to another is solely due to the difference of the electric tension at both these points; and further, that the quantity which passes is proportional to this difference of tension, it follows that the positive fluid proceeding from A right to *c*, and the negative fluid proceeding from A left to *c*, must decrease in tension the further they recede from A. The tension of the electricity at every point in the circuit may be represented by a diagram. Let the ring be suppposed

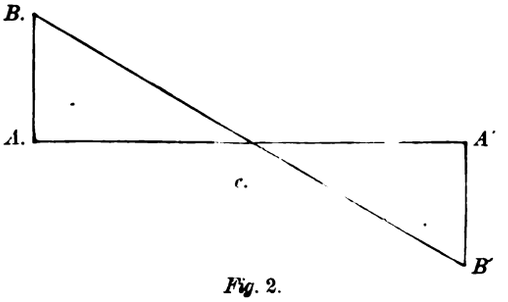

Fig. 2.

stretched out into a straight line, AA (figure 2); let the ordinate AB represent the tension of the positive electricity, and A´B´ the tension of the negative electricity at the point of excitation, then the ring being homogeneous and of the same diameter throughout, the straight line BB´ will express the tension for all points of the circuit.

From these considerations, the law of Ohm expressed by the celebrated formula $S=\frac{E}{R}$ where S represents the strength of the current, E the electro motive force of the battery, and R the resistance, naturally follow. If the electromotive force AB+A´B´ remain constant, then the greater the length of AA´ the less steep will be the inclination of the line BB´; that is to say, the less will be the difference o tension in two contiguous cross sections. But by the hypothesis, this difference is proportional to the quantity of fluid which passes from one cross section to another; and hence it follows that the greater the length of the circuit, the less will be the amount of electricity which passes through any cross section in a given space of time.

If the conductor AA´ be composed of material which offers a greater resistance to the passage of the electricity than that above supposed, as long as its length remains unaltered, the distribution of the electricity will be the same. But inasmuch as the moving force—that is, the difference of tension between two neighboring cross sections—is also the same as before, a less quantity of electricity must pass from section to section in a given time than in the case of a good conductor; or, in other words the current must be weaker. A greater le-

Digitized by Google

the better conductor would produce precisely the same effect. These results find definite expression in the law, that *the strength of the current is inversely proportional to the resistance of the circuit.* Preserving the length and material of AA′′ unchanged, and regarding the force AA′+BB′ as variable, we deduce the law that *the strength of the current is directly proportional to the electromotive force.*

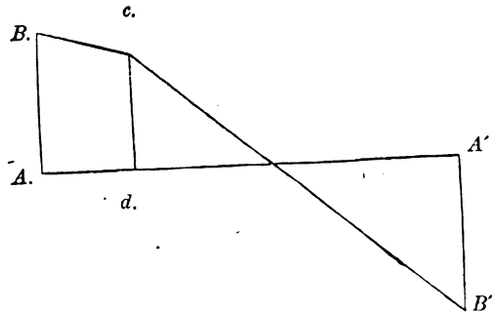

Fig. 3.

Let the conductor AA′ (fig. 3) consist of the same material throughout, but of two portions possessing different cross sections. Let the cross section of Ad, for example, be *m* times that of dA′; then, if equal quantities pass through all sections in equal times, if through a unit of length of wire of *m* times the cross section, no more fluid passes than through the thinner wire, the difference of tension at both ends of this unit of length in the former must be only $\frac{1}{m}$th of what it is in the latter. Thus the electric fall, as Ohm terms it—that is, the decrease in the length of the ordinate for the unit of length of the abscissa, will be less in the case of the thick wire than of the thin, as shown by the line Bc in the figure. The distribution of the electricity in such a circuit will be no longer represented by a continuous gradient, but can nevertheless be easily ascertained by calculation when the electromotive force of the circuit and the cross sections of its different portions are known. If, instead of one wire being thinner than the other, its specific resistance were greater, it would follow from the hypothesis of Ohm, that the greater the resistance of the metal, the greater would be the electric fall. The result is summed up in the law, that *the electric fall is directly proportional to the specific resistances of the metals, and inversely as their cross sections.*

To ascertain by experiment whether the actual distribution of electricity throughout a galvanic circuit bore any resemblance to that theorized by Ohm, M. Kohlrausch used an electrometer of surpassing delicacy, consisting of a thin needle of silver wire, two inches in length, suspended horizontally from a glass fibre of exceeding fineness. The fibre, which passed in the usual manner through a glass tube, was fastened to a torsion head, the index of which being turned, caused the little needle of silver wire at the other end to follow it. The needle lay across a thin slip of silver of its own length, through a slit in the centre of which it could descend. At the slit the strip was bent right and left, so that the needle, in following the index, could lay its entire length against the strip. When the needle crossed the strip at right angles, the latter was raised so that the needle rested upon it, the apparatus thus forming a continuous cross of conducting material. Electricity being communicated to the strip, distributed itself over the entire cross. When this was affected, the strip was lowered so that the needle again hung free. The index above being turned, the needle was compelled by the torsion of the fibre to approach the strip, but being charged with a like electricity, was repelled. By this play of torsion on the one hand, and repulsion on the other, a knowledge is obtained of the tension of the electricity communicated.

In connection with the electrometer, a condenser was made use of, the accuracy of which was carefully tested beforehand. For experiments with the galvanic circuit, both plates were of brass, suspended in a suitable frame by strings of silk, and separated from each other by shell-lac placed at three different points near the periphery. When the poles of the battery were connected with these plates, the one became charged with positive, the other with negative electricity, and the strength of the charge was estimated by removing one of the plates to a certain fixed distance, and bringing the other, by means of an isolated copper wire, into connection with the electrometer. The question suggested itself to Kohlrausch, whether any relation existed between the electromotive force of a voltaic element (which Ohm expresses in his formula by the letter E) and the tension of the electricity of the two poles of the element. The electromotive forces of various combinations were determined by Wheatestone's method. To ascertain the tension of the poles, the circuit, which had remained in action for some time, was suddenly broken, and the ends of the wire were brought into connection with the plates of the condenser. The plates were then separated, and one of them immediately brought into connection with the electrometer, and the strength of the charge measured. The results derived from this process established the important fact, *that the electromotive force is proportional to the electric tension at the ends of the newly-broken circuit.*

EFFECTS OF ELECTRICITY ON MILK.

The *Milk Journal* states that, in an address before the North Western Dairyman's Association, Mr. X. A. Williard repeats the following interesting facts:

Mr. Andrew Cross, the celebrated English Experimenter, considered that the roots and leaves of plants were in opposite states of electricity; some of his experiments in this direction are very interesting. He cut two branches from a rose tree. They were as nearly alike as possible, with the same number of buds, and both equally blown. An arrangement was made by which a negative current of electricity was passed through one, a positive current through the other. In a few hours the negative rose drooped and died, but the positive continued its freshness for nearly a fortnight; the rose itself became full blown and the buds expanded, and survived an unusual length of time. Again, he was able to keep milk sweet for three weeks in the hottest weather of summer, by the application of a current of positive electricity.

On one occasion, he kept fishes under the electric action for three months, and at the end of that time they were sent to a friend, whose domestic knew nothing of the experiment. Before the cook dressed them, her master asked her whether she thought they were fresh, as he had some doubts. She replied, that she was sure they were fresh, indeed, she said, she would swear they were alive yesterday. When served at table, they appeared like ordinary fish, but when the family attempted to eat them, they were found to be perfectly tasteless; the electrical action had taken away all the essential oil, leaving the fish unfit for food. However, the process is exceedingly useful for keeping fish, meats, etc., fresh and good for ten days or a fortnight. Now this is consistent with our observation and the facts known to every one in the habit of handling milk. When the condition of the atmosphere is in a negative electrical state, or shows a deficiency of positive electricity, a state of whether which we designate as sultry, close, muggy, and the like, there is always difficulty in keeping milk sound. Even in good, healthy milk, the fungus germs common to all milk increase and multiply with great rapidity, producing the common lactic acid fermentation or souring of the fluid; but in case fungi from decomposing animal or vegetable matter comes in contact with the milk, rapid decomposition takes place, and we have rotten milk, putrid odors, and floating curds. The exposing of such curds to the atmosphere, as well as the aeration of milk to improve its condition, are both philosophical, because these minute organisms of fungi are affected by the oxygen of the air, which checks their development and multiplication.

The influence of electrical action is a question entirely new to the dairy public, but it is one concerning which I think some useful suggestions present themselves for our consideration. When the electrical equilibrium is disturbed, or when the state of the atmosphere indicates a preponderance of negative electricity, we are all made aware of the fact by its depressing influences. At such times it is important that we take more than ordinary care in the handling of milk; that it be kept out of harmful odors; that attention be given to its aeration, and such treatment be given it as shall be inimical to the growth and development of fungi. And again, the fact that milk may be kept sweet a long time in hot weather by electrical action will offer a very important suggestion to inventors in the preservation of milk, and perhaps in the improvement of cheese at the factories. I believe that we are only on the threshold of the cheese making art, and that as we become better acquainted with the laws of Nature and their application, great progress is yet to be made in every branch of dairy husbandry.

CHINESE BY TELEGRAPH.

The managers of a telegraph company in China, have recently solved the problem how to transmit telegraphic messages in Chinese. At first sight the difficulty of an alphabet which is made up of about fifty thousand distinct characters, appears almost insurmontable, but the obstacles have been overcome, and A-Fat, at Hong Kong, encounters no more difficulty in communicating with A-Chum, at Shangai, than does Brown with Jones, under similar circumstances. The plan adopted is this: Some few thousands of the more common Chinese characters are cut on wooden blocks after the manner of type, and on the reverse end of each is a number cut in the same way. Now A-Fat, having handed in his message written in Chinese, the native clerk selects in order the corresponding blocks from the case, and prints off the numbers on their reverse. This he hands to his English colleague, who telegraphs the numbers to the destination desired. Here the reverse process is gone through, and, the numbers having been taken from the cases, the characters are stamped on paper, and thus A-Chum is put in possession of the cherished wishes of A-Fat through the medium of his native language.

PRESENTATION.—A meeting of the Liverpool telegraphists was held on Saturday evening, a few weeks since, for the purpose of presenting a testimonial to Mr. W. H. Evans, for many years connected with the late Magnetic Telegraph Company, and until recently in the service of the postal authorities on the electricians' staff, he being about to leave England for Canada. The presentation took the form of a highly illuminated address, a beautiful gold locket (subscribed for by the ladies connected with the department), scarf-pin, designed by Mr. Jacobs, Church-street; and a copy of Shakspeare's works handsomely bound.

WESTERN UNION TELEGRAPH OFFICE, AT ERIE, PA. THE NEW LOCATION IN THE ROSENZWEIG BLOCK.

Among the many improvements made this spring, denoting business prosperity, is that of the Western Union Telegraph Company, which has removed from its inconvenient second story rooms, to the ground floor, State street front, of the Rosenzweig Block, which has been fitted up in a style somewhat in consonance with the large business done. The room is 20x42 feet. The counter that bounds the reception room is an L shape, fifteen feet each way, and is of chestnut, ornamented with strips of walnut. Above the counter there is a railing of handsome scroll work, and this is covered with wire gauze. In the receiving room is a chestnut table, supported by brackets, that is one of the nicest plain pieces of joiner work to be found anywhere. The operating room is supplied with three walnut operating tables, six feet long and thirty inches wide, with scroll work back.

Last, but not least to the telegraphic eye, there is a new switch board, with upwards of four hundred bright brass cranks on its surface, the use of which is a mystery to the uninitiated, but which control, to the use of the various machines, the news from the ten wires leading into the establishment. The "local batteries," of which they now have six in position, are the Callaud (French) patent, emit no smell, and do not need renewing oftener than once in six months.

WESTERN UNION TELEGRAPH OFFICE AT MEMPHIS, TENN.—THE NEW LOCATION ON MADISON STREET.

The new office of the Western Union Telegraph Company, at No. 33 Madison street, between Main and Second, has been opened for business. The business apartments occupy the first floor, where Mr. Glynn Baker, the Manager, has his quarters; the second floor by Colonel James Coleman, the Superintendent, and the third by the operators.

In 1847, Colonel Coleman built the first telegraph line that connected Memphis with the world. It extended from Nashville via Columbia, Waynesboro, Purdy, Somerville and Raleigh to Memphis. Now there are twenty-two lines, covering every point of the compass.

Quite a number of gentlemen of the press and other citizens were invited to inspect the new quarters, which they did, and were highly pleased with the completeness and adaptation of the office for the business. After they were through, an adjournment was had to the "National," next door, where an enormous bowl of champagne punch, provided by Colonel Coleman, was discussed.

Glynn M. Baker, Manager; P. J. Murray, Receiving Clerk; Chas. Gaston, Delivery Clerk; Joe Whitney, Book-keeper; Chas. Marable, Assistant Book-keeper; Lindsey Mynatt, Assistant; Dick O. Dyer, Chief Operator; Joe Fowler, Assistant Chief Operator; Chris. Reilly, Marco F. Paoli, Alf. Saville, Cornelius McCarthy, S. M. Dunlap, C. Paxson, Day Operators; Howell Sigler, Charles H. Patch, M. G. Chettle, P. J. Fowler, Charles Curry, Night Operators; Willie Kirk, Operator, Commercial News Department; Henry Joyce, Assistant in the office; William Brown, Check Boy, and six Messengers; Dan Shay, Foreman of Repairs; Charles Clements, Battery Man.

The operators are all of the first-class, and most competent and accomplished gentlemen. None are employed except men of the first order and highly qualified.

There are nine single tables for one wire each, and two double tables, each holding two sets of Phelps' self-breaking repeaters.

SUN STROKE.

Sun stroke and stroke of lightning, says Dr. Hall, as far as present light extends, cause death in the same manner; the blood is expanded and gases are liberated, both tending to distend the veins, which causes in the brain a species of apoplexy; this distension of blood vessels induces pressure on the brain, and consequently all loss of sense and feeling; the muscles are paralyzed, all motion ceases, and the functions of the body are all arrested.

Apply cold cloths or ice bags to the head, and mustard plaster to the neck, with something to act on the bowels as soon as possible. But something more speedy than this is an imperative necessity in most cases, or death will ensue in a few moments. Skillful and eminent physicians in this country, upon actual experiment, founded upon a true philosophy, have ascertained that speedy recovery takes place, within an hour, if the patient is bled from both arms in the old-fashioned way. From the largest distended vein the blood may only flow by drops at the first second or two, but as it flows freer, the relief becomes almost miraculous, and speedy and complete.

WHAT TO DO IF THE CLOTHES TAKE FIRE.

So many accidents are daily occurring from broken kerosene lamps, and clothes taking fire from gas lights and open fire-places, that the following, which we clip from an exchange, deserves attention: Perhaps three persons out of four would rush right up to the burning individual, and begin to paw with their hands without any aim. It is useless to tell the victim to do this or that, or call for water. In fact, it is generally best not to say a word, but seize a blanket from a bed, or a cloak, or any woolen fabric—if none is at hand, take any woolen material—hold the corners as far apart as you can, stretch them higher than your head, and running boldly to the person, make a motion of clasping in the arms, just about the shoulders. This instantly smothers the fire and saves the face. The next instant throw the unfortunate person on the floor. This is an additional safety to the face and breath, and any remnant of flame can be put out more leisurely. The next moment immerse the burned part in sweet oil. Next get some common flour, and put it on the burn, about an inch in thickness, and if possible put the patient to bed. Let the flour remain until it falls off itself, when a beautiful new skin will be found. Unless the burns are deep, no other application is needed. Dry flour for burns is the most admirable remedy ever proposed, and the information ought to be imparted to all. Dredge on the flour till no more will stick, and cover with cotton batting.

PAPER CLOTHING.—An English inventor is said to have produced a really serviceable paper fabric. It is a mixture of various animal and vegetable substances, the former being wool, silk and skins; the latter, flax, jute, hemp and cotton. These articles are all reduced to a fine pulp, bleached, and then felted, by means of machinery. The mixture of these several substances produces a fabric claimed to be of wonderful flexibility and strength, so much so that it can be sewed together with a machine as are woven fabrics, and make as strong a seam.

This paper can be made into table cloths, napkins, handkerchiefs, pants, curtains, shirts, and other articles of dress. The petticoats made from it are said to be of elaborate design and wonderful beauty. The United States *Economist* says they are either printed or stamped, and bear so close a resemblance to linen or cotton goods of like description, as almost to defy the scrutiny of the ablest experts. The stamped open-work skirts display a delicacy of pattern that it would be almost impossible to imitate by any ordinary skill with the needle. Imitation blankets, and chintz for beds, furniture, or curtains, are also made very cheaply. Embossed table cloths and figured napkins made of felted paper, so closely resemble the genuine damask linen, as to be palmed off upon the unsuspecting as the genuine article.

In Germany, paper napkins have been used for several years. Their cost is but a trifle, and they pay for themselves before they require to be cast aside. Felted paper is capable of being made into lace, fringe and trimming; and for these several purposes it is unequaled in point of cheapness and durability. Imitation leather is also made from the same material, which is also impervious to water. It is soft and pliable, and is a useful fabric for covering furniture, making into shoes, for belts, and many other purposes. In China and Japan, paper clothing has long been worn by the inhabitants. It is very cheaply produced there, a good paper coat costing only ten cents, while the expense of an entire suit is limited to twenty-five cents.

ANCIENT MODES OF WRITING.—Some of the earliest methods of writing are singular evidences of the progress of civilization. Bricks, tiles, star-shells, ivory, bark, and leaves of trees were used to write on; and from the latter, leaves of books are probably derived. Copper and brass plates were early in use, and a bill of feoffment on copper was some years since discovered in India, bearing date one hundred years B. C. Leather was also used, as well as wooden tablets. Then the papyrus came in vogue, and about the eighth century the papyrus was superceded by parchment. Paper, however, is of great antiquity, especially among the Chinese; but the first paper mill in England was built in 1586, by a German, in Kent. Nevertheless, it was nearly a century and a half, namely, in 1713, before Thomas Watkins, a stationer, brought paper making to anything like perfection. The first approach to a pen was a stylus, a kind of iron bodkin; but the Romans forbade its use, on account of its frequent and even fatal use in quarrels, and then it was made of bone. Subsequently reeds, pointed and split, like pens in the present day, were used.

HERE are some railroad statistics that will be somewhat surprising to the people who are perpetually declaiming about the criminal carelessness of our railroad managers, and wondering why our roads cannot be run with as great care and safety as those of Europe. The statistics of persons killed or injured on railroads, when tabulated, present the following startling result:

British railroads, one in	430,000
Massachusetts railroads, one in	1,475,000
Belgian railroads, one in	1,600,000
Prussian railroads, one in	3,000,000
French railroads, one in	4,000,000

Men are deceived in this matter by the immense disproportion between American and European travel. Our roads are crowded with business. On the great trunk lines out of New York trains follow each other almost within sight. And the newspapers gather up in one issue accidents spread over an entire continent. In Europe travel is less, the roads are less crowded, there are fewer of them, and the newspapers know less of the accidents which take place upon them. Probably Massachusetts railroads are exceptionally safe; but the dangers of railroad traveling are greatly overrated. Some statistician has estimated that a man must travel several millions of miles before it becomes his turn to be killed or injured.

Sweden	4,048	10,089	99	187	494,111	224,200	201,540	24,940	226,480
Switzerland	3,203	6,866	483	63	1,329,061	251,432	213,130	27,480	240,610
Turkey	15,827	26,381	348	45	457,993	1,010,184	874,217	100,971	975,188
Great Britain and Ireland	29,746	130,008	2,000	1,780	10,084,020	3,865,127	2,277,195	4,486,166	6,763,362
Indo-European	2,115	3,418	10	...	41,000	281,250	340,000	....	340,000
British India	14,939	24,538	197	537	512,648	599,713	1,224,587	331,312	1,555,899
Totals	167,055	439,468	7,248	6,048	31,311,001	$14,455,352	$13,387,488	$6,287,998	$19,675,487

We give above the results of the operation of the principal government telegraphs in Europe and Asia for 1870. The receipts and expenses in Great Britain and Ireland are for fourteen months. These figures show that the expenses exceeded the receipts by $5,220,135, and that the cost of transmitting the messages averaged 63 cents. These facts are not very favorable for Government Telegraphy in an economical point of view. It will probably be claimed that a portion of the expenses was incurred in the construction of new lines, and should not properly be charged to working expenses. If there is to be a yearly deficit for this account for an indefinite period, however, it would seem to be proper to include it in the expense column, especially as there is no return whatever for the vast amount invested in the construction of the lines. The fact is that Government Telegraphs are an expensive luxury, which only monarchical and personal governments can really afford to indulge in.

NEW THEORY OF ATMOSPHERIC ELECTRICITY.

A correspondent, Mr. G. Wright, of Rock Falls, writes as follows:

"The earth is surrounded by an electrical atmosphere which is subject to the law of gravitation, and is consequently more dense near the surface of the earth, and more rare in the higher regions. All the phenomena of electricity are due to the disturbance of this electrical atmosphere, in connection with the resistance of different substances to the passage of the electric fluid. When any substance has more electricity than another substance near it, it is in a positive or charged condition; when it has less, it is in a negative condition, and the attraction which negative substances exhibit for the positive is only the tendency to restore the equilibrium.

If a bladder be filled with air near the surface of the earth, and then elevated to a considerable distance, the confined air will burst the bladder and escape, because the atmosphere which surrounds it in these higher regions is of less density. So if a metallic ball, having the electrical condition natural to the surface of the earth, be suddenly elevated, its natural electricity becomes a charge, which may be drawn off by a spark. This fact can be demonstrated, on a still day when the air is free from moisture. Now, what better evidence do we want to prove that the earth is surrounded by an electrical atmosphere, more dense near the surface of the earth, and that the charge on the ball which was elevated is due to the lesser density of the electrical atmosphere which there surrounds it? When we add to this the chain of evidence which results from the explanation, of electricity in the clouds, the causes of *aurora polaris*, the daily variation of the magnetic needle, and every other electrical phenomenon, on this hypothesis, the proof is as positive that the earth is surrounded with an electrical atmosphere as that it is surrounded with an aerial one. I have spent several years in experiments and observations to demonstrate the truth of this hypothesis, and upon it to establish a theory that shall be applicable to all electrical experiments and phenomena, and am astonished at the facility with which all questions pertaining to this subject can be solved.—*Scientific American.*

CARBOLIC ACID NOT A PERFECT DISINFECTANT.—A writer in the *English Mechanic* advises its readers not to put implicit faith in carbolic acid as a disinfectant, as he believes its merits to have been greatly overrated. As a deodorizer he considers it far inferior to ordinary chloride of lime, the effect lasting only a short time. He finds that the vapor of chloride is very much superior for the purpose, as it always destroys the vitality of infectious and diseased germs, which carbolic acid does not. To completely disinfect an apartment that has been occupied by a patient suffering under small-pox, typhus fever, or other disease, it is only necessary to vacate the apartment after stopping up the openings, and placing in different parts of the room several plates containing a quantity of common salt on which a little vitriol has been poured. The vapor of chlorine will be instantly nvolved, and will annihilate all infection with which it comes in contact. It may be used even in rooms containing sick persons, if the quantity evolved be so slight as not to inconvenience the lungs of the patient.

CORRESPONDENCE.

MORE ABOUT TRAIN DISPATCHING.

COLUMBUS, Ohio, June 6th, 1872.

To the Editor of the Journal of the Telegraph:

In the train dispatchers' controversy, which has of late had quite a conspicuous part in your columns, allow me to deposit my mite. Not claiming fifteen years in dispatching trains, yet the short experience I have had in dispatching trains has brought many kinds of systems under close observation. I have found the "double order" system very efficient on roads where schedules were few, where operators were very punctual, and if many sections on the schedules close together. Where many freight trains are running from and against passenger trains, it is necessary, with the "double order" system, to send a copy of each freight train's order to said passenger train; while a "single style" (or "old man's" order system) one order, sent to the agent, operator, or conductor, at the station where said passenger train is to come from, to "hold such passenger train for orders," would be the best way. Thus, according to the "old gentleman's" single system, all the trains on the division could be moved on the one order given to the train when ready to leave, otherwise the passenger train, if many trains were moved against or ahead of them, would have a stack of unnecessary orders, which could be sent as one, saving both time and trouble. As regards positive meeting points, I would add that it depends much on the running rights of trains—whether or not the detention likely to occur from the delayed train would throw the favored train from its next meeting point—otherwise a time order would give one of them a right to proceed. I fail to see where the communication from the L. M. Division "covers the contested ground" which A. T. L. claims by his correspondence of the 7th ult. Train dispatchers should adopt a system best suited for the working of their divisions, where operators are indifferent to their work, have a mania for sleep, and practice it, irrespective of delayed trains. Dispatchers, as a general rule, think themselves fortunate to get a "single" order to them. Brevity should be the aim of every good dispatcher.

CONTROVERSY.

POSTAL TELEGRAPHS.

MONTREAL, 3d June, 1872.

To the Editor of the Journal of the Telegraph:

I have read with much interest the correspondence in the JOURNAL regarding the scheme which is on foot for transferring the telegraphs to the United States Government; and having recently arrived from the old country, where I was in the service of the English Government on the electrician staff, I may perhaps be allowed to say a few words on the subject.

Yielding to the pressure brought to bear by the newspaper press and news room proprietors, who were clamoring for cheap telegraphy, the Government instructed Mr. Scudamore to prepare a scheme whereby the telegraphs of Great Britain and Ireland could be worked by the postal authorities. Ample time was allowed for the preparation of this plan, yet it was apparent, from the great muddle which took place on the day of the transfer, that it was sadly defective, and the folly of entrusting the control of telegraphs to men who were totally ignorant of the working of this most important branch of the public service was at once apparent.

Granted that the rates for sending messages were considerably reduced; but at what cost to the public was this so-called boon obtained? Messages were delayed until they were useless; slow registering or recording instruments were substituted for rapid sound instruments; operators refused to work under managers who did not know their business, their places being filled by incompetent hands, which led to numerous errors; and, indeed, such was the disgraceful state of affairs that, had the Government, in framing the Telegraph Act, not rendered it illegal for private parties to run telegraph wires, and thus destroy their monopoly, a new line would have at once been created by the commercial public, who were great sufferers by the new régimen.

This derangement of a concern which had hitherto given the greatest satisfaction in its working to the majority of the public, and which was kept in efficiency by healthy competition, continued for a period of nine months, by which time the postal authorities were commencing to know a few of the intricacies of the electrical telegraph, and things ran pretty smoothly until December last, when a Government official wilfully delayed some important press telegrams, and, although he had rendered himself liable to twelve months' imprisonment, he was not prosecuted, and in the House of Commons his conduct was excused by the Postmaster General.

I think I have shown that if governing bodies are determined to take over telegraphic concerns, the public must be prepared for vexatious delays, and they also give the party in power a weapon which they will not be slow to use in times of electioneering excitement, and whenever it suits their purpose.

This agitation will materially depreciate the value of the company's stock in the market; and I have yet to learn that it is a wise policy on the part of any Government, by means of the power which it has at command, to take over wholesale and monopolise a concern which flourishes and gives the greatest satisfaction, owing to the enterprise and courage shown by its promoters.—I am, Sir, your obedient servant,

W. H. E.

CLEAR CREEK, Texas, June 12, 1872.

To the Editor of the Journal of the Telegraph:

The following message was received at B—.

N——, May 30th, 1872.

To H. B. Ryan, B—

Come to N—— immediately; very important. The operator will please have this delivered at once. Mr. Ryan will pay cost of delivering.

(Signed),

22 Paid. R. B. LOVE.

Now, Mr. Ryan lives at a point in the country fifteen miles from B—. Should the operator have the message delivered to Mr. Ryan, at a cost of five or six dollars? If Mr. Ryan refused to pay this, could the operator force him to do so? I say he could not, as he is not supposed to know the contents of a message, and should not act on that part of the message intended for him.

Please answer this through the JOURNAL, and oblige

C. C. C. Jr.

Answer.—Rule 10 prescribes, that whenever a message is to be forwarded by express or delivered by special messenger beyond the limits of office delivery, the receiver shall collect for such service and add the amount to the check, and the office receiving the same will check the amount against the transmitting office, the same as for *other lines*.

Managers may, upon receiving a deposit of money sufficient to cover all expenses, undertake to have messages delivered by special messenger, from any point at which this company has an office.

No receiver should take in a message requiring special delivery at some other office, without receiving a deposit sufficient to cover the cost of such special delivery, or unless such expense is guaranteed by a responsible party.

In a case like the above the receiver makes himself responsible for the cost of delivering the message, if the party to whom it was addressed should refuse to pay for it.

Mr. Ryan could not be compelled to pay for the delivery of the message, since he did not ask to have the service performed, nor can any person to whom a collect message is sent, be compelled to pay the charge, unless it is an answer to a message sent by such person, the charges upon which, had been guaranteed in advance. The office which sends a collect message, or a message with orders to collect for delivery, becomes responsible for the amount in case the person to whom it is addressed, refuses to pay the charges.

To the Editor of the Journal of the Telegraph:

Will you please inform me through the columns of the JOURNAL, how I may be enabled to make a good lightning arrester for the protection of my relay during thunder storms? By so doing, you will much oblige AMATEUR.

June 13, 1872.

Answer.—Lightning arresters are kept in stock by the Western Union Company, and can be obtained by any office by requisition upon the Superintendent. Until one is received, "Amateur" had better cut his relay out of circuit when in danger of damage from lightning.

To the Editor of the Journal of the Telegraph:

You will oblige me greatly by answering the following question:

Has a telegraph operator the right to go in a Western Union Telegraph Office, or in any other telegraph office, and send a message dead head?

D. J. R.

Answer.—No operator has the right to send a message free, unless it is approved by the manager of the office where the message originates. Rule 48 reads as follows:

"Private messages between the employees of the Company, must be restricted to those of an urgent social character, and approved by the Manager of the office from which they are sent. Copies of such messages must be regularly checked, and returned with other free business."

ANSWERS TO CORRESPONDENTS.

WHENEVER a Red message is received, Saturday night or Sunday morning, at any station where there is a Sunday delivery, it should be delivered on Sunday morning, the same as any other message; but Red messages should not be received from the customers for transmission, on Saturday night, with the promise of a Sunday morning delivery.

THERE are ten words in the following message: "Twenty-two John street, up stairs; with Starrs & Marcus."

IN a message signed "Smith & Jones, per Jones," the appendix to the signature should be counted if the customer desires its transmission.

THERE are nine words in the following message: "One hundred and fifty (150) dollars."

SELMA, Ala., June 26, 1872.

To the Editor of the Journal of the Telegraph:

In your issue of the 15th, there is a communication regarding the whereabouts of R. J. Fowler. Please state that I am, and have been for the last five years, at Selma, Ala.

Respectfully yours,

ROBERT J. FOWLER,
P. O Box 141.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JOURNAL OF THE TELEGRAPH,

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, JULY 1, 1872.

CONGRESS AND THE POSTAL TELEGRAPH SCHEMES.

Congress has adjourned, and the various telegraph properties are safe from spoliation for a while longer. It is amazing to see the equanimity with which the Senate Post Office Committee has discussed and recommended a scheme so much akin to robbery, under the specious plea of public benefit.

It was Johnson, we believe, who defined the term "patriotism" as the last resort of scoundrels, and while we are not prepared to condemn in so sweeping a manner the action of the parties engaged in this latest attempt to scoop in for their own private ends the vast business built up by the energy and foresight of the existing telegraph companies, yet we cannot help believing that if the great cynic could once again assume his earthly existence, and becoming cognizant of the facts in connection with the schemes of the day to legalize the appropriation of the fruits of the labors of other men, under the guise of benefitting the dear people, he would see nothing to modify in the severity of his definition.

Of course we have here in view the so-called "Hubbard" scheme of Postal Telegraphs, which modestly calls upon Congress to create that *distinguished philanthropist* and his associates into a body corporate, and to grant to them full and plenary power to take possession and control of all telegraph property, and to operate it for their own private benefit.

Under this scheme, the owners of the telegraph property are to receive no adequate compensation for the rich prize which is so easily to drop into the hands of this fortunate lobbyist, while the public is to pay roundly through the post office department for the performance of the telegraph service. To the credit of the various House Committees who have had this scheme under consideration for the past four years, it must be said that they have never yet reported inits favor, or given it any countenance whatever, and we trust that they never will. But in the consideration of this scheme, many valuable hours have been wasted, and probably many more will be in future; while at every session of Congress the telegraph companies are required, at much expense and trouble, to defend their property against this insidious parasite, which seeks to attain its subsistence at the expense of the telegraph interests, to which it has dishonestly attached itself.

Among the recent resignations from the service of the Western Union Telegraph Company, is that of Mr. John Horn, Jr., for the last seven years Manager of the office in the New York Stock Exchange, who, on the first of June, entered his name among the list of the "bulls" and "bears" of Wall street. Mr. Horn was one of the oldest and best known operators in the country. In the new field he has entered, he has our best wishes for his success.

The excellence of the "Putt Mechanical Telegraph Instrument," and its adaptibility for the purpose for which it is intended, is well set forth in our advertising columns. During the past year there has been sold twelve hundred of these machines, and for the present the stock is exhausted,

So much for first class references and advertising in the Journal.

By referring to our advertising columns, it will be seen that "The Telegraph Supply and Manufacturing Company, Geo. B. Hicks, President," have succeeded to the business of the firm of Hicks & Shawk of Cleveland, O. The business of the late firm had increased so largely that their facilities were totally inadequate to meet it. The enlargement of facilities and the ample capital at command, with the well-known ability of Mr. Hicks, cannot fail to ensure success.

The new company also succeed to the business of "The Automatic Fire Alarm Company of Ohio."

Mr. Geo. F. Durant has been appointed Superintendent of the New York Division of the American District Telegraph Company.

The Telegraph during the Philadelphia Convention.—The Western Union Telegraph Company transmitted over their wires during Wednesday and yesterday the enormous number of 983,742 words of report to the newspaper press of the country. The regular business was in no manner interfered with by this marvellous achievement.—*Phila. Enquirer.*

Since 1865 the Great Eastern has been exclusively devoted to submarine telegraphic purposes, and during that time has laid in various parts of the world, no less than 20,000 miles of deep-sea electric cable, all of which is now in good working order. The capital invested in those various cables, is estimated at $35,000,000. This huge vessel was alone capable of affording the accommodations required for stowing away the thousands of miles of heavy cable necessary, and, above all, she alone was found to possess the evenness requisite for paying it out without difficulty or disaster. She has laid down submarine cables in all parts of the world. The British, Australian, China, Submarine, British Indian, and British Indian Extension, are only a few of the enterprises in which she has been engaged. She has traversed the Pacific, the Southern and Indian Oceans, as well as the Atlantic, in her errand of civilization.

Post Office Telegraphs.—The total number of messages forwarded from Postal Telegraph stations in the United Kingdom during the week ending the 1st of June, 1872, and during the corresponding week of 1871. Week ended 1st June, 1872, 288,400; week ended 3d June, 1871, 202,049; increase in the week of 1872 on that of 1871, 86,351.

At the meeting of the Inventors' Institute at London, on Thursday Evening, May 23d, Mr. F. H. Varley, F.R.A.S., read a paper on inventions relating to telegraphy. After explaining the early attempts to establish telegraphy by Sir Francis Ronalds, and its practical introduction by Sir F. Cooke and Sir C. Wheatstone, and referring to the improvements of Mr. Cromwell Varley in insulators, some of which were exhibited, and after alluding to various systems of telegraphs, instruments of an entirely new construction, invented by the reader and his brother Theophilus Varley, were exhibited, comprising a new form of key instrument for transmitting messages. A relay regulator was displayed, for controlling an electric current in a manner not unlike the govenor of a steam engine, so that when the current flowing into the relay is too powerful for rapid working, the magnetism developed is at once cut off. An improvement was also shown in the ink-writing Morse instrument, which consisted in the substitution of a self-feeding and repointing pencil rotating by clockwork for the ink-wheel arangement. It was explained that the durability of a pencil-marked was such that ¾ of an inch of the black cylinder would last a month on the busiest circuits.

A prospectus has been issued of the Economic Telegram Company (Limited), with a capital of £150,000, in shares of £15, to purchase and carry out invention by which nearly all kinds of telegraphic messages "can be so effectually condensed as to send with perfect accuracy from five to ten ordinary telegrams as one." The business of the Company will be merely that of an agency, involving no costs of construction or maintenance of cable wires. Under these circumstances, as the sum to be paid for the invention is not stated, the necessity for raising such an amount of capital as £150,000, is not perfectly clear.

Hydro-Electric Submarine Cable.—M. Ferdinand Tommasi, 69, Avenue de l'Alma, Paris, an engineer and inventor of considerable eminence and repute, has just perfected an invention under the above title, which is attracting attention, and likely to excite considerable interest. He proposes to employ it for submarine telegraphy, and to substitute for the ordinary electric conducter, the cable, a simple tube of copper, containing, as it were, a thread or column of water, which is stated to transmit effectually and instantaneously every impulse communicated by pistons, and not only that, but to permit such impulses to be transmitted in opposite directions at the same time. M. Tommasi's experiments have been conducted upon a limited scale, but he affirms that he can absolutely obtain the following results:—1. A speed of transmission of 600 signals per minute, even at 4000 kilometres distance, (nearly 2500 miles English). 2. Simultaneous exchange of correspondence, any number of dispatches being effected at once by the same cable. 3. Adaptability to any recording instrument whatever, Quadrant, Morse, Printing, &c., quite automatically. 4. Economy in first cost, durability, and increase in returns.

The actual duration of a flash of lightning does not exceed the millionth part of a second. But the retina of the human eye retains the impression of the electrical flash for a much longer period.

MEASURING THE VELOCITY OF ROTATION.—Professor A. E. Dolbear suggests, in the *American Journal of Science*, a simple and effective method of determining the velocity of rotation of wheels and shafts. Upon the face, or upon the periphery of the rotating object, he fastens smoked paper, and this he touches with a point of rubber which is attached to one branch of a vibrating tuning-fork, having a known rate of vibration. The fork is to be so held that the direction of its vibrations will be at right angles to the line of motion of the shaft. By counting the number of undulations made, on a given extent of the smoked paper, the speed of rotation is at once indicated. Thus, if the fork makes 100 vibrations in a second, and one vibration is recorded on the smoked paper, in a space covering one-half the circumference of the wheel or shaft, or two vibrations within the entire circumference, it is evident that the rate of rotation is 50 revolutions per second. By this simple and easy method the velocity of rotation of gyroscope disks, and of all kinds of shafts and wheels, may be readily ascertained.

ICE FROM FIRE.—A platina crucible is made and, maintained red hot over a large spirit lamp. Some sulphuric acid is poured into it. This acid, though at common temperature one of the most volatile of known bodies, possesses the singular property of remaining fixed in the red-hot crucible, and not a drop of it evaporates; in fact, it is not in contact with the crucible, but has an atmosphere of its own interposed. A few drops of water are now added to the sulphurous acid in the red-hot crucible. The diluted acid gets into immediate contact with the heated metal, instantly flashes off, and such is the rapidity and energy of the evaporation that the water remains behind, and is frozen into a lump of ice in a hot crucible, from which, seizing it the moment before it again melts, it may be thrown out before the eye of the astonished observer. This is, indeed, "a piece of natural magic," and as much like a miracle as any operation of the forces of nature could produce. It is certainly one of the most singularly-beautiful experiments imaginable.

BORN.

HORNE.—June 12, 1872, to O. A. Horne, Manager W. U. Telegraph Office, Cuthbert Ga., a son.

HAYGOOD.—June 15, 1872, to A. Watts Haygood, Manager W. U. Telegraph Office, Fort Gaines, Clay Co., Ga., a son.

LYNCH.—June 15, 1872, to Frank J. Lynch, Manager W. U. Telegraph Office, West Point, Neb., a daughter.

THOMPSON.—May 18, 1872, to F. T. Thompson, Manager W. U. Telegraph Office, Lynn, Ill., a daughter.

MARRIED.

BURLEY—WEST.—In Philadelphia, June 6, 1872, by Rev. E. G. Brooks, William S. Burley, Western Union Stock Board Office, to Corina Florence, daughter of Mr. James West.

CHRISTY—GREEN.—At Jamesville, N. Y., May 2, 1872, by Rev. J. W. Watson, Charles H. Christy, Manager W. U. Telegraph Office, Jamesville, N. Y., to Miss Augusta E. Green of same place.

HOPCRAFT—HICKMAN.—June 4, 1872, at Pittsburgh, Pa., Mr. James Hopcraft, Train Dispatcher C. B. & Q. R. R., Galesburg, Ill., to Miss Mattie Hickman, of Chariton, Iowa.

MCKEE—JACKSON.—At Seville, O., May 27, 1872, by Rev. T. C. Warner, T. F. McKee, operator at Palestine, O., to Miss Florence Jackson of Loudonville, Ashland Co., O.

DIED.

ENGLERTH.—In Savannah, Ga., May 18, 1872, Harry W., infant son of Joseph A. Englerth, formerly of Martinsburg, W. Va., aged 15 months.

PIERSON.—Wednesday, June 19, 1872, at Olney, Ill., J. Knox Pierson, in the 34th year of his age.

WILLIAMS.—June 20, 1872, at Baltimore, Md., of consumption, Rudolph R. Williams, of the Franklin Telegraph Co., aged 23 years, 5 months, and 15 days.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
July 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since June 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

* Aldrich, Minn.
* Anthon, Minn.
Aulac, N. B., tariff same as Sackville, N. B.
* Big Coolie, Dac.
374 Bogue Chitto, Miss.
158 Beattie, Ks., re-opened.
309 Bridgeport, Ill.
* Bar Harbor, Mount Desert, Me., re-opened, tariff same as heretofore.
* Chaska, Minn.
6 Danforth, Me.
480 Douglass, Texas.
47 Englishtown, N. J., check Jamesburg, N. J.
* Farmington, Utah.
* Georgetown, Minn.
* Glyndon, Minn.
* Glenbeulah, Wis.
Hutchinson, Ks., tariff 10c. more than Newton, Ks.
* Hawley, Minn.
45 Hart's Falls, N. Y.
367 Hale, Iowa.
359 Hematite, Mo.
* Island Lake, Minn.
* Juniata, Neb.
* Kimbles, Pa.
* Kimberly, Minn.
* Lakeside, Minn.
* Lavalle, Wis.
* Little Coolie, Dac.
* Moorhead, Minn.
* Mountain Lake, Minn.
* New London, Wis.
* Oakfield, Wis.
358 Pleasant Plains, Ill.
* Perham, Minn.
* Princeton, Wis.
* Pickets, Wis.
367 Rome, Jones County, Iowa.
46 Rosendale, N. Y., heretofore an Other Line office.
* Randon Lake, Wis.
Sedgwick City, Ks., tariff 10c. more than Newton, Ks.
337 Rochester, Ill.
397 Shocks, Iowa,
* Sauk Centre, Minn.
* Seymour, Wis.
* Sioux City Junction, Minn.
298 St. Mary, Ill.
465 St. Francis, Kansas.
150 Shaws, Pa.
159 Shenango, Pa.
* Thomson, Minn.
Wichita, Kansas, tariff 10c. more than Newton, Ks.
* Wadena, Minn.
* Waldo, Wis.
* Wauwatosa, Wis.
* Withington, Minn.
* Wellsboro, Pa.

SUMMER OFFICES RE-OPENED.

27 Bethlehem, N. H.
27 Crawford House, N. H.
46 Cornwall, N. Y.
27 Glen House, N. H.
23 Gorham, N. H.
20 Jackson, N. H.
169 Little Mountain, O.
40 Lebanon Springs, N. Y.
37 Lake Mahopac, N. Y.
27 Mount Washington, N. H.
27 Mount Washington Depot, N. H.
67 Mount Pleasant, Del.
* Narragansett Pier, R. I.
* Overlook Mountain House, N. Y.
Point-du-Chene, N. B.
27 Profile House, N. H.
* Rocky Point, R. I.
* Spencer Springs, N. Y.
27 Twin Mountain House, N. H.
143 Yellow Sulphur Springs, Va.
20 White Mountain House, N. H.
27 Waumbeck House, Jefferson N. H.

Business for Twin Mountain House, White Mountain House and Mount Washington Depot, N. H., should be checked to Crawford House, N. H., and Mount Washington, N. H., to Glen, House, N. H.

The tariff to or from the "Summer Offices" in N. H. named above, "except Gorham" is 20 cents more than present rate by "square." Tariff to Gorham from offices in Vt. and N. H., will be 20c. more than square rate; from all other offices tariff will be 25 and 1 "for other lines" from Portland, Me. check Portland.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.		*Leaves this Line.*
Aldrich, Minn.,	150	10	Chicago, Ill.
Anthon, Minn.	150	10	"
Big Coolie, Dac.,	200	13	"
Chaska, Minn.,	100	7	"
Farmington, Utah,	50	20*	Salt Lake City, Utah.
Georgetown, Minn.,	200	13	Chicago, Ill.
Glenbeulah, Wis.,	50	8	"
Glyndon, Minn.,	200	13	"
Hawley, Minn.,	200	13	"
Island Lake, Minn.,	150	10	"
Juniata, Neb.,	155	10	Plattsmouth, Neb.
Kimbles, Pa.,	20	2	Honesdale, Pa.
Kimberly, Minn.,	150	10	Chicago, Ill.
Lakeside, Minn.,	200	13	"
Lavalle, Wis.,	60	4	"
Little Coolie, Dac.,	200	13	"
Moorhead, Minn.,	200	13	"
Mountain Lake, Minn.,	150	10	"
New London, Wis.,	75	5	"
Oakfield, Wis.,	50	8	"
Perham, Minn.,	150	10	"
Princeton, Wis.,	60	4	"
Pickets, Wis.,	60	4	"
Randon Lake, Wis.,	35	2	"
Sauk Centre, Minn.,	150	10	"
Seymour, Wis.,	75	5	"
Sioux City Junc., Minn.,	100	7	"
Thompson, Minn.,	150	10	"
Wadena, Minn.,	150	10	"
Waldo, Wis.,	35	2	"
Wauwatosa, Wis.,	35	2	"
Withington, Minn.,	150	10	"
Wellsboro, Pa.,	35	2	Corning, N. Y.

* Additional five words or less.

OFFICES CLOSED.

Kingston, Md., Kirkwood, Del., Oakwood, Texas, and Stewartsville, N. J.

GENERAL INFORMATION.

The name of the office heretofore known as Windham Station, O., has been changed to Mahoning, O., and Calhoun, O., changed to Windham, O.; and Crow Wing, Minn., changed to Motley, Minn., and that of Oak Lake, Minn., changed to Audubon, Minn.

Covington, Va., will hereafter be checked as an Other Line Office, "Tariff for Other Lines" 65 and 4 from Richmond, Va., check Richmond, also Milford, Pa., with "Tariff from Other Lines" 20 and 2 from Port Jervis, N. Y., check Port Jervis, N. Y.

The following offices will hereafter be checked direct: South New Market, N. H., Burnham and Clinton, Me.

Hereafter the "Tariff for Other Lines" to Overlook Mountain House and Woodstock, N. Y., will be 35 and 2 from Rondout, N. Y.

The P. O. address of Shenango, Pa., is "Shenango," Greenville, Pa., P. O.

The tariff to square 6 will be 10 cents more than to square 10.

The office at 377 Rome, Iowa, is in Henry Co.

OFFICES HAVING "SPECIAL SHEET A"

Will hereafter check Logan Iron Works, Lewistown, Pa., same as "special rate," to Lewistown, Pa.

WILLIAM ORTON, President.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, June 29, 1872.

On and after July 8, *Baldwinsville, N. Y.*, will be added to the list of Money Order offices in Transfer Agent S. B. Gifford's District.

G. H. MUMFORD, Vice-President.

TELEGRAPHERS' INSURANCE ASSOCIATION.

The acknowledgment of receipt on any one assessment is to be understood as an acknowledgment for all previous assessments.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 16. NEW YORK, JULY 15, 1872. WHOLE NO. 113.

GALVANOMETERS.

Professor Œrsted, of Copenhagen, discovered in the year 1819 that a magnet, freely suspended, tends to assume a position at right angles to the direction of a current of electricity passing near it.

If a magnetic needle is poised upon a pivot, so as to allow a free horizontal motion, and a wire, whose direction is north and south, and which is traversed by an electric current, passes directly over and parallel to it, the needle will be deflected towards the east, or west, according to the direction of the current. If the wire is placed in the same direction below the needle, the deflection will be the reverse of that produced by the same current when flowing above. If the current is passing from south to north in the wire, the north pole of the needle will turn to the west when below the wire, and to the east when above it.

The manner in which a needle should turn when influenced by a current is easily kept in mind by Ampere's rule: suppose the diminutive figure of a man be placed in the circuit, so that the current shall enter by his feet and leave by his head, when he faces the needle, its north pole always turns to his left. If the current enters by his head, under the same conditions, the north pole of the needle will turn to his right.

In the accompanying illustrations the figure of the man is represented by the wire *A*, *B*, and the needle by *N*, *S*. In figure 1 the current enters by his feet. and in figure 2 by his head. If the needle were placed on the other side of the wire its deflection would be reversed.

Fig. 1.

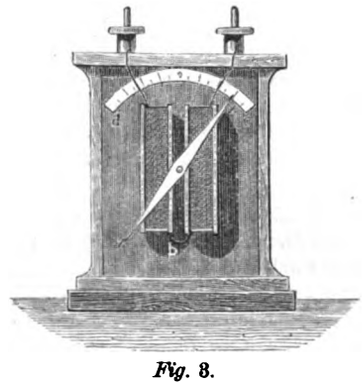

Fig. 2.

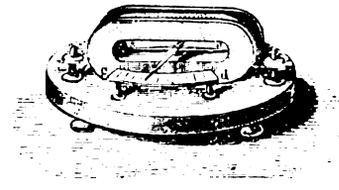
When a magnetic needle is placed under a straight wire, through which a current passes, it deflects to a certain extent, and when the wire is bent so as also to pass below the needle it deflects still more. This is easily understood from the above rule. The supposed figure has to look down to the needle when in the upper wire, and to look up to it in the lower wire, so that his left hand is turned in different ways in the two positions.

The current in the upper and lower wire moves in opposite directions, thus changing in the same way as the figure, and the deflection caused by both wires is in the same direction. By thus doubling the wire the deflecting force is doubled. If the wire be carried a second time around the needle, the effect will be again doubled, and by a still further increase in the number of turns a corresponding increase in force will be obtained. Thus a very feeble current, whose action would be scarcely sensible if the wire by which it is transmitted made but one convolution, is able to exert a very marked action when the number of convolutions becomes considerable. This is done by insulating the wire so that the different convolutions may be juxtaposed and superposed, without causing a direct metallic communition from one convolution to another, and thus compel the current to traverse its entire length. This apparatus, which was original with Schweigger, is called a galvanometer, and affords the most convenient and accurate means for measuring the strength of a galvanic current which has ever been devised.



Galvanometers are made in many forms and for various purposes. In some cases the needle hangs vertically, and is kept in its normal position by gravitation, the lower end being heavier than the upper; while in other cases the needle is poised in a horizontal position like that of a mariner's compass, or supended by means of a silk fiber.

The vertical galvanometer (fig. 3) requires no adjustment, as the north end of the inner needle is made sufficiently heavy to keep it in a vertical position; but it is not as sensitive as the other forms, and as the force with which a current acts upon it depends on its magnetism, which is constantly decreasing, its indications vary from time to time.

Fig. 3.

In the above cut *Z*, *Z* represent the needle, whose angle of deflection is proportional to the quantity of electricity flowing through the coils, the direction in which it moves indicating the direction of the current. The scale *d*, *e*, is divided into two equal parts in the centre of which is the *o* point where the upper portion of the needle rests, when no current is passing through the coils; from the *o* point the scale is divided to the right and left into degrees, by means of which the angle of deflection of the needle can be read.

In a horizontal galvanometer the needle is kept in its place by its tendency to point north and south through the action of the earth's magnetism, and therefore the feebler the magnetism of the needle the less resistance will it offer to being moved by the current, while on the other hand the current acts with less force on a feeble magnet, and thus the instrument remains constant. In constructing a horizontal galvanometer (fig. 4) the wire is coiled

Fig. 4.

round a wooden or metal frame, so as to leave between its lower and upper surface the smallest possible space, in the interior of which the magnetised needle *s*, *n*, is suspended. The angle or number of degrees through which the magnetised needle is moved is indicated upon the scale *e*, *d*, by the pointer *z*, and shows the quantity of electricity passing through the coils, while the direction in which it moves, indicates the direction of the current.

In order to increase the sensibility of the galvanometer, Professor Cummings suggested the idea of neutralising the directive force of terrestial magnetism by employing two needles, as nearly alike as possible, placed parallel to each other, with their poles in opposite directions and suspended so as to move freely by a thread without torsion. Magnets so arranged have little tendency to place themselves in the magnetic meridian, as the one would move in a contrary direction to the other. If they were of exactly the same power they would remain indifferently in any position. As they cannot, however, be so accurately poised as this they always take up a fixed position, arising from the one being somewhat stronger than the other. Such a compound needle is called astatic, as it stands apart from the directing magnetic influence of the earth.

If an astatic needle be placed in a coil, so that the lower needle be within the coil and the upper one above it, its deflection will be greater than a single needle, because the power which keeps the needle in its fixed position is small and the needle is more easily influenced; and also because the force of the current is exerted in the same direction on two needles instead of one.

An astatic needle so placed in a coil constitutes an astatic galvanometer. The upper needle moves on a graduated circle, from which the number of degrees that the needle deflects may be read off. When deflection takes place the different portions of the coil are differently situated with respect to the needle from what they are at zero, and therefore

Digitized by Google

the deflecting force of the coil differs with the position of the needle, so that the deflection caused by different currents are not proportional to the angles of deviation above 20°.

There is another circumstance which prevents the angle of deviation from being proportional to the quantity of current passing through the galvanometer, viz.: that the directive force of the globe, which, by tending to bring back the needles into the magnetic meridian, produces equilibrium with the force of the current that moves it from it, is proportional, not to the angles, but to the sines of the angles of deviation; and that from about 20° the difference between the arc and its sine, becomes too considerable to permit of their being taken indifferently for each other.

In the sine galvanometer or in the tangent galvanometer these sources of error are avoided. The sine galvanometer is composed: first, of a vertical metallic circle *G*, *H*, (fig. 5), having upon its circum-

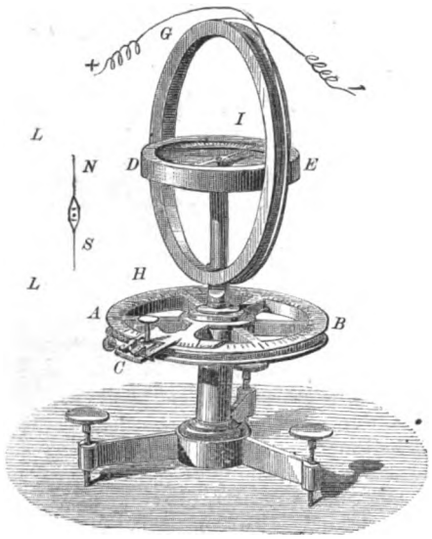


Fig. 5.

ference an orifice sufficiently deep and wide to contain the insulated wire which is wound round the circle and constitutes the coil; second, of a magnetised needle *I*, poised upon a pivot in the middle of the circle *E*, *D*, and which receives the influence of the multiplicator; third, of a divided circle *A*, *B*, maintained in a perfectly horizontal position, and over which the movable transom *C*, carries the multiplicator *G*, *H*, and its needle. A system of levels and binding screws permits of the establishment of the rigorous horizontal of the circle *A*, *B*. The instrument is placed north and south, and when the circle *G*, *H*, and the magnetic needle are both in the plane of the magnetic meridian, the apparatus is at the zero of the division. When a current is sent through the wire which surrounds the circle *G*, *H*, the needle is deviated in proportion to the magnetic force which is induced by the current. The transom that carries the multiplier is then turned until it is brought again into the plane of the needle. In order to conveniently observe the exact direction of the needle a copper pointer with an index line is fixed at right angles upon it. The needle is exactly parallel to the mean plane of the multiplier when the index line of the pointer falls beneath the wire of a lense that is fixed to the movable piece upon which the galvanometer is adjusted. When the needle is deviated by the passage of the current through the multiplier, the transom is turned until the wire of the lense coincides with the index line, and the division traced upon the fixed circle indicates the number of degrees it was necessary to turn it from 0 in order to obtain this coincidence. The strength of the current is proportional to the sine of the angle measured upon the circle *A*, *B*, by the movement of the alidade *C*.

In this apparatus the needle preserves the same position in relation to the current which consequently acts upon it in the same manner. The extent of the deviation must depend therefore solely upon the quantity of the current passing through the galvanometer.

As the sensitiveness of the apparatus depends upon the number of convolutions of the conducting wire upon the circle, it can be made applicable to any strength of current by increasing or diminishing the number of convolutions.

THE AIR FILTER.

Professor Tyndall, after a long series of experiments with atmospheric air, concluded that many of our most formidable diseases, such, for example, as small pox, cholera, and typhoid were propagated by the flotation of invisible particles in the atmosphere, and that, by the use of a suitable breath filter, it would be practicable for any person to enter an infected apartment without danger. The same apparatus, he stated, might be used by firemen, enabling them to enter buildings filled with dense smoke without injury, as the filter would arrest the particles of carbon, of which smoke is composed, allowing only the air to pass into the lungs. A further use of the breath filter is to facilitate miners in exploring and working in mines where carbonic acid gas is present in noxious proportions.

A recent trial of filters, made substantially as suggested by Professor Tyndall, has lately taken place in England, and we will describe some of the results. The filter itself consists of a cylinder, four or five inches long and two inches or more in diameter. Its interior contains, at the top, a layer of cotton wool which has been moistened with glycerine, then a layer of dry cotton wool, then a layer of charcoal, then cotton wool, with wire gauze covers at both ends, and at the upper end a mouth piece so shaped as to fit closely over the mouth of the wearer. By drawing the breath through this instrument, the most dense smoke may be entered with impunity. This filter has been tested by the London Fire Department with such success that the firemen of that city are to be provided with it for regular use. When places are to be entered, such as mines or wells, where carbonic acid is present, it is necessary to add another layer of cotton wool, and to place a layer of slaked lime between the two bottom layers of cotton. The object of the lime is to arrest the carbonic acid and oxide gases.

A recent test consisted in placing the experimenter, who had one of the instruments secured over his mouth, within a small closet, with a rabbit and two birds for companions. Carbonic acid gas and carbonic oxide were then injected until the atmosphere of the closet was rendered highly poisonous. In twenty-three minutes, the animals were dead, but the experimenter came out at the end of thirty minutes, having suffered no inconvenience from the noxious gases; but the work of breathing through the small instrument for so long a period and the heat of so small an apartment rendered him uncomfortable. Experiments are still in progress to determine the best sizes and forms for the instrument, and ere long we may expect that the air filter will be an instrument of common use.

A WONDERFUL MACHINE.

The pin machine is one of the closest approaches that mechanics have made to the dexterity of the human hand. A small machine about the height and seize of a lady's sewing machine, only much stronger, stands before you. On the side, at the back, a light belt descends from a long shaft at the ceiling that drives all the machines, ranged in rows on the floor. On the left of our machine hangs, on a little peg, a small reel of wire, that has been straightened by running through a compound system of small rollers. The wire descends, and the end of it enters the machine. This is the food consumed by this snappish, voracious little dwarf. He pulls it in and bites it off by the inches incessantly—140 bites to the minute. Just as he seizes each bite, a saucy little hammer, with a concave face, hits the end of the wire three times, and "upsets" it to a head, while he grips it in a countersink hole with his teeth. With an outward thrust of his tongue he lays the pin sideways in a little groove across the rim of a small wheel that slowly revolves just under his nose. By the external pressure of a stationery hoop these pins roll in their places as they are carried under two series of small files, three in each. These files grow finer toward the end of the series. They lie at a straight inclination on the pins, and by a series of cams, levers and springs, are made to play like lightning. Thus the pins are dropped in a little shower in a box. Twenty-eight pounds is a day's work for one of these jerking little automatons. Two very intelligent machines reject every crooked pin, even the slightest irregularity of form being detected. Another automaton assorts half-a-dozen lengths in as many boxes, all at once, and unerringly, when a careless operator has mixed the contents of boxes from various machines. Lastly, a perfect genius of a machine hangs the pins by the head in an inclined platform through as many "slots" as there are pins in a row of paper. These "slots" converge into the exact space spanning the length of a row. Under them runs the strip of pin paper. A barb like part of the machine catches one pin from each of the slots as it falls, and by one movement stick them all through the corrugated ridges in the paper.

Electric Gas Lighting.—In order to insure as far as possible the safety of the gunpowder works at the Royal Arsenal, Woolwich, England, the gas-lamps are in future to be lighted by means of electricity. This process has already been adopted at the cannon cartridge factories, and several other workshops, where the quantity of explosive material is necessarily large, and it is understood to be intended to apply this system to all the buildings in the Royal Arsenal, where work of a similar nature is carried on. The whole of the lamps by which these workshops are lighted, are invariably fixed outside the windows, and open only on the outside of the building; but it has been thought that lighting them by the ordinary means is nevertheless attended with danger, and their ignition by wires in connection with a galvanic battery, will be the means of insuring greater security against accidents.

A communication has been made to the Philosophical Society of Manchester on the destruction of a church by lightning, in which clear particulars are given of the metallic connections, and of the behavior of the shock when it fell. The author states, in closing his paper, that in districts where gas mains, and water mains and pipes are laid underground, all buildings may be entirely protected by connecting the lightning conductors directly with the two sets of mains. Had this been done, he says, at the church in question, it would not have suffered.

QUANTITY AND TENSION.

The term *quantity* has a well understood meaning; it conveys an analogous idea when applied to electricity, to that which it does when applied to water or to a gas; thus, two similarly charged Leyden jars, or two miles of submarine cable, contain twice the quantity that one does, and if the charges of both can be placed into one, the quantity remains unaltered, the only thing affected being the intensity or tension. If a pair of galvanic plates one inch square give a certain quantity of electricity in a unit of time, a pair of two square inches will produce twice the quantity, provided the plates are connected by very short and thick wire, for if connected by a very fine or long wire the quantity will be smaller, and if not connected at all none will be produced. In the latter case the quantity produced will be exactly that quantity which the connecting wire can convey from one to the other, and hence it arises that the quantity produced by a battery is generally proportional to the length and size of the connecting wire.

The effect exerted by electricity is in almost every case proportional to the *quantity* of electricity *in action*, and has no relation whatever to its intensity or tension.

On *quantity alone* depends the action of all telegraphic apparatus, which operates with more or less vigor according to the greater or less quantity of electricity passing through. If we increase intensity, we do so only with the view of making a larger quantity pass through the line, the quantity increasing in the same ratio that the intensity increases.

Electroscopic attraction and repulsion have not been hitherto considered by writers on electricity to be in any degree simply dependent on quantity, but to depend on the tension, or, as it is termed, the intensity of the charge; but a careful examination of the phenomena can scarcely fail to lead to the conclusion that the force varies *directly as the tension, directly as the quantity, and inversely as the distance.*

Intensity signifies difference or degree of tension, or that effect which is produced by increasing the number of cells in a battery; but in its more popular acceptation it has a very different value, and the effects of quantity are entirely confounded with those of intensity. Every condition and quality of electricity is expressible by the relations of quantity and tension, and they are equally applicable to all its states, whether static or dynamic. The earth is always referred to as the standard of tension.

The earth, however, does not always exhibit the same tension at all places. Nor does it always have the same tension at any given place. What are familiarly known to telegraphists as "earth currents" in their wires are evidences of this, and are produced by the flow of electricity between two points on the earth's surface, which are at the time in an unequal state of tension; the flow continues until the tension has equalized itself. During the prevalence of aurora these electrical compensations proceed incessantly, and sometimes rise to a magnificent scale. Vast floods of electricity flow through the earth and the ocean, chasing each other to and fro in the most capricious manner, the currents being sometimes so great as to fill the telegraph lines with currents as powerful as those yielded by a battery of 300 or 400 cells.

The mean tension of the earth, however, when free from these exceptional disturbances, may be taken as a standard of tension, its zero, like that of heat, being unattainable; we cannot determine the absolute tension of electricity, and, therefore, in speaking of the tension of objects, we mean their relative tension.

Wherever there are differences of tension and conductors there are currents of electricity set up, and these continue until the tension has equalized itself, and thus inequality of tension is the essential condition and cause of all electric currents. If we connect the negative pole of a battery of, say, 100 cells to earth, its positive pole instantly exhibits a tension of 100 elements plus, or above, that of the earth; if we reverse the battery, its negative pole presents a tension of 100 elements minus, or below, that of the earth.

If a battery of, say, 200 cells be perfectly insulated, it is impossible to predicate what may be the tension of either of its poles; all we know for certain is, that the tension of its positive pole is 200 elements above that of its negative, and that the tension regularly increases from cell to cell. If we touch any part of the battery with an earth wire, that part instantly acquires the same tension as the earth; thus, if touched at the centre, its poles are respectively 100 elements above and below that of the earth; if at 50 cells from the positive end, the poles respectively acquire tensions of 50 plus and 150 minus, and so on; all this time no current is flowing and the tensions are purely statical.

If one end of a long piece of wood or string be applied to the pole of a very powerful battery of, say, 500 cells, and the other end to the ground, the one end will have the same tension as the battery, the other will have that of the earth; and, if we apply an electrometer at successive points along the rod, we shall find every possible degree of tension exhibited from that of the battery to zero. This is an exact illustration of what takes place in a telegraph cable.

The amount of electricity which flows through a wire depends wholly on the relative tension of its two ends, and not on its absolute tension with respect to the earth. For example, a single cell of a battery connected by a wire transmits a given quantity of electricity when it is in its ordinary condition, and its tension therefore zero. If this element and its galvanometer be placed on the prime conductor of an electric machine, and the tension of the whole system be raised to two or three thousand elements above that of the earth, the quantity of electricity which passes is not affected, nor is the indication of the galvanometer. Again, if we connect a powerful battery with a very long wire, and place a galvanometer in circuit, first at the end near the battery, and afterwards at the end near the earth, or in any other part of the wire, we shall find its deflection precisely the same in all positions, although the tension at the extreme ends has been shown to be so different. We thus see that the indications of the galvanometer are not at all affected by the absolute tension of the point of the line at which it is connected.

If we form a galvanometer with only one turn of very thick wire, and note the deflection caused by one cell of moderate size, and then successively increase the number of cells, arranging them in series, we shall not, by so doing, find any increase whatever in the deflection of the needle, for the thick wire conveys freely all the electricity which one cell can produce, and the additional cells can only increase the tension, they cannot increase the quantity. If, on the other hand, a galvanometer be formed of a great number of turns of very fine wire, the deflection will be immensely greater with numerous cells. With a great length of fine wire the tension of one cell is only sufficient to transmit a small proportion of the quantity which it is capable of producing; by increasing the number of cells, however, the tension becomes sufficient to overcome the resistance; and whatever the length or fineness of the wire, there is some number of elements sufficiently great to cause as much electricity to pass in a unit of time as the one original plate caused to pass through the thick wire.

With dynamic electricity, the *quantity* of electricity which passes in a given time determines the amount of galvanic deflection, or electro-magnetic attraction, or chemical decomposition, or of the attraction of one current upon another, or of heat generated in a wire or a voltaic arc, and the *difference of tension* determines the velocity of electricity, or, in other words, the quantity which flows through a circuit in a given time. The tension, therefore, indirectly enhances all the phenomena above mentioned.

With static electricity the *quantity* of electricity on a given surface determines the amount of electroscopic attraction and repulsion, and it determines the degree of tension while the *tension* reciprocally determine the amount of attraction and repulsion, and also the quantity of electricity which will be stored up inductively on a given surface. And in all the above cases the degree of action varies in simple proportion to the quantities, or, in the case of repulsion, to the quantity and tension combined.

STATISTICS OF TELEGRAPHY.—At a recent meeting of the London Statistical Society a paper was read by Sir J. Anderson upon "The Statistics of Telegraphy." The paper embraced two subjects—first, the effect of reduced tariffs upon telegraphy, and, second, the merits of the various cables that have been invented. A table was exhibited showing that a private company, previous to the purchase by the Post-office of the land line, had reduced their tariff several times and made a profit of 7 per cent.; but it was shown in a second table that had the same company not reduced its tariff, it would have earned 17 per cent. Most of the arguments which Sir James Anderson adduced went to prove that a reduction of tariff led to a diminution of the net product. The kingdom of Belgium was cited as an example, it being stated that the most reliable statistics were obtained from this country. With regard to the *materiel* of the submarine cables, Sir J. Anderson said that he was strongly in favor of the old-fashioned and expensive manufactures. They were invariably more durable, and were found to be cheaper in the end, than the new and cheap cables. The report of the joint committee which was appointed by the Lords of the Committee of the Privy Council, eleven years ago, to investigate the matter, showed that in almost all cases small cables had been found liable to mishaps, while the heavier the cable had been, the greater had been its durability. Mr. Newall had said in his evidence that a hemp-covered cable which he had attempted to lay was destroyed in two years. It was stated in the paper that all cables which were manufactured and laid down upon the principles which were established in 1859 were at the present time in good working order, and every divergence from these principles had been at best a costly experiment or an utter failure. Sir James Anderson was of opinion—and the opinion was shared in by Captain Halpin—that it was advisable to multiply every precaution which should increase the strength of the cable, and to keep the strength intact as long as possible. Finally, he believed that the so-called economy would be at the expense of security, and that the cable of the future would be even heavier, more perfect, and more costly than the cable of the present day.

FOREIGN TELEGRAPHIC ITEMS

POST OFFICE TELEGRAMS.—The total number of messages forwarded from Postal Telegraph stations in the United Kingdom during the week ending the 8th June, 1872, and during the corresponding week of 1871. Week ending 8th June, 1872, 286,687; week ending 10th June, 1871 (Ascot Race week), 222,490; increase in the week of 1872 on that of 1871, 64,197.

The statement showing the total number of messages forwarded from Postal Telegram stations in the United Kingdom during the week ending the 15th of June, 1872, and during the corresponding week of 1871, was: June 15, 1872, 298,957; June 19, 1871, 225,198; increase, 73,759.

THE TELEGRAPH TO AUSTRALIA.—Notice has just been issued by the Post-office that a telegraphic message of twenty words can be sent to Queensland, in Australia, for £10, and that it will be forwarded to Port Darwin by cable, and thence to its destination by horse express and telegraph. The whole distance which such a message will travel will be some 14,000 miles, and it will reach its destination in about thirty hours. It will go from London to the land's end on land wires, and will enter the sea and reappear at Alexandria, pass over Egypt, re-enter the sea at Suez, and again appear at Port Darwin.

With respect to the alternative line from Port Darwin to Adelaide, projected in the report of the British Australian Telegraph Company, it is well to know that the Queensland Government have asked the Legislature for authority to guarantee interest on the cost of a second cable from Batavia to Queensland. Resolutions to that effect were moved last April in the Legislative Assembly by the Prime Minister, Mr. Palmer, and were favorably received. Those resolutions, and the Act of Parliament carrying them out, have, it is assumed, by this time been passed. As all the telegraph lines in the Australian colonies are State lines, the Queensland Government will naturally divert all the messages upon the guaranteed line, in order to cover its guarantee, and any branch line from Port Darwin to Queensland, such as is proposed by the British Australian Company, could, therefore, it is contended, only command even a portion of the business flowing from Europe to Queensland and the eastern colonies, and none of that flowing from the latter to Europe. The former business would be quite inadequate to prove remunerative, and the necessity for this extension has been altogether superseded by the action of the Queensland Government. Unless that decision be reversed, of which there seems no likelihood, the Queensland Government would not allow the branch cable to land, as it would carry off some of the business, and would render it more likely that the Government would have to pay some portion of the guaranteed interest. Meantime the British Australian Company's line across the continent approaches completion, and so narrow is the gap that the company is now prepared to send messages from the north to the south of the island. Since writing the the above we have been informed that the directors have received notice that their cable between Java and Port Darwin is interrupted, and advice that messages for Australia, New Zealand, and Tasmania should for the present be sent by post, *via* Galle.

THE TELEGRAPH IN NEW ZEALAND.—Telegraphic communication is at last completed from end to end of the islands, by the extension of the line to Auckland. Speaking of this important and long delayed work, one of the leading journals of the colony justly remarks: "The completion of the telegraph to Auckland is a subject for no ordinary congratulation. All the important towns and settlements in the colony now enjoy the advantages of instant communication with each other. For years the work of connecting Auckland with the rest of the colony has been embarrassed by obstacles of vexacious and not easily surmountable character. The difficulties have arisen from the fact that the wire had to pass for a considerable distance through the lands of natives jealous in the extreme of European influence, and fanatically opposed to anything calculated to infringe their exclusiveness. But by continuous diplomatic persuasion, and a happy mixture of pressure and conciliation, the prejudices of the natives have been overcome, and now the talking wire has broken down another of the barriers to the progress of civilization in native regions."

CONTINENTAL RATES.—It is understood that the Submarine Telegraph Company have for some time past contemplated making a large reduction in their tariff to the Continent, and that with this object negotiations are in progress with the French Government (subject to the approval of Her Majesty's Postmaster-General) for a mutual reduction of rates, which, if carried into effect, will establish a uniform charge between all telegraph stations in France and in Great Britain; besides which, they hope to effect a considerable reduction in the through rates to Italy, Spain and the South of Europe. As the diminution in the charge of telegraph messages has hitherto invariably produced a large increase of business, it may be anticipated that, in adopting these liberal measures, the Submarine Company will add to their own revenue, while, at the same time, they will confer a great boon on the public, and more especially on the mercantile community.—*London Railway News.*

TELEGRAPH ACROSS THE ANDES.—According to the last advices from Buenos Ayres, the Trans-Andine Telegraph was expected to be completed in a few days, so as to establish immediate communication between the Southern Pacific States and the Atlantic. The impetus thus likely to be given to the progress of Chili, Bolivia, Peru, and the Argentine Republic can hardly be overestimated. In other directions similar work is actively going on. "The Bolivian Government," says the Buenos Ayres *Standard*, "is laying down wires to meet ours at Jujuy, and the Paraguayan has notified President Sarmeinto that its main line will soon touch the Argentine at Paso la Patria." At the same time connection with the Uruguayan Republic from a line from the Argentine province of Entre Rios will speedily be in operation, and meanwhile, with regard to the working of the communications at present opened, it is said "the low tariff fixed by Government has led to such an enormous growth of business in the interior that two wires are wholly insufficient, and five more are necessary." The clerks in the various offices, it is added, work fourteen hours daily, and yet, although the staff in some places has been trebled, can scarcely clear of the accumulation of messages.

CABLE EARNINGS.—The companies owning and operating lines of trans-Atlantic telegraph have certainly no good reason to complain that their property is not profitable. At the recent annual meeting of the Societe du Cable Trans-Atlantique Francais, it was announced that the balance of profits due the shareholders upon the earnings of 1871 was £189,836, or a dividend of 12 per cent., besides leaving £24,295 to be added to the reserve fund. It will be remembered that the French company endeavored, when their line was projected, to secure assistance in laying it from the Anglo-American company, which was at first refused. Subsequently, however, an arrangement was completed, according to which the Anglo-American company was to receive 52 per cent. of the receipts and the French company 48 per cent. It is out of this share that the 12 per cent. dividend to stockholders has been declared. At the recent annual meeting of the Telegraph Construction Company the accounts showed a devisible profit which, with the division previously made, gave the shareholders for 1871 25 per cent.

THE Eastern nations of Europe are waking up on the subject of submarine telegraphy. It is announced that the Czar of Russia and the Sultan of Turkey have come to the conclusion of establishing telegraphic communication between Odessa and Constantinople, by means of a cable underneath the waters of the Black Sea. The starting point of the cable will be on the European shore of the Black Sea, at the mouth of the Bosphorus. The work will be finished within a year.

DR. JOULE, in some experiments lately made on the polarization, by frictional electricity, of platinum plates, has found that charge which they received was only diminished one-half after an interval of an hour and a quarter. The plates were either immersed in water or were laid in alternate series, separated by wet silk. The amount of charge they took was measured by means of a delicate galvanometer. He has suggested that a condenser on this principal might be useful in researches on atmospheric electricity.

OBITUARY.

SAMUEL C. BISHOP.

It is with no ordinary feeling of sorrow that we announce the death of Samuel C. Bishop, late proprietor of the Bishop Gutta Percha Works, who died in this city on the evening of the 4th of July last. Mr. Bishop has for many years been well known to the telegraphic fraternity as the manufacturer of submarine telegraph cables and insulated wires, for electrical and telegraphic purposes.

He was in ordinary health up to within a few days of his death, when he was somewhat prostrated by the excessive heat, and remained at home as a precautionary measure, but was not considered seriously indisposed until the day of his decease. His remains were taken to Boston, Mass., and now rest in the beautiful cemetery of Mount Auburn, where they were deposited on Tuesday last. He leaves a wife, but no children, to mourn his death.

BORN.

AYRES—June 24, 1872, to H. S. Ayres, chief operator West Penn. R. R., Blairsville, Pa., a daughter.

MOSES.—June 29, 1872, to J. N. Moses, Manager W. U. Telegraph Office, Laramie City, Wy., a son.

MARRIED.

BEELER—WEST.—At Brookfield, Mo., May 29, 1872, by Rev. W. S. Cooper, T. S. Beeler, Train Dispacher H. & St. J. R. R., to Miss Carrie R. West, of Brookfield.

BELL—POOR.—At Reno, Nev., on Tuesday, July 2, 1872, Frank Bell, Manager W. U. Telegraph Office, Reno, to Mary P. Poor, of same place.

MOORE—RILEY.—In Industry, Pa., July 9th, 1872, by Rev. W. L. Wortman, Jno. E. Moore, East Liverpool, Ohio, to Miss Mattie E. Riley, formerly Operator at Industry, Pa.

STEWART—DIEL.—At Sedalia, Mo., June 20, 1872, by Rev. J. Brown, A. M. Stewart, Operator W. U. Telegraph Office, Pleasant Valley, O., to Miss Lizzie Diel, of Sedalia. No Cards.

DIED.

LOGAN.—In Birmingham, Mich., June 19, 1872, of consumption, Mary E., wife of William J. Logan, aged 25 years and 5 months.

MILER.—At Williamsburgh, L. I., July 6, 1872, Willie Vincent, infant son of Thomas M. and Anna Miler, aged 4 months and 26 days.

Digitized by Google

CORRESPONDENCE.

FOLLOWING COPY.

SAVANNAH, Ga., July 1, 1872.

To the Editor of the Journal of the Telegraph:

The position which "Buffalo" has assumed appears to be somewhat indefinite in its intent. It might be inferred that he means, that if an employee of the company is absolutely certain that the message is wrong, he ought to be permitted to exercise his judgment in correcting it, in order to prevent reproach or injury to the company by delaying the message for subsequent correction or delivery, is palpably erroneous. But, as no operator absolutely knows a message which has been sent to him for transmission to be wrong, it would appear that "Buffalo" believes in abiding by the company's regulations, verbatim, rather than permit him to exercise his opinion as to its correctness.

The point he has in view may, however, be this: ought an operator, under any circumstances, be permitted to exercise his judgment in matters appertaining to the interests of the company employing him? This question is a very nice one, and its discussion would no doubt prove very interesting in its various aspects. People's judgment are so variable, their views of questions so different, that what might appear just and reasonable on the part of one, would appear diametrically opposite to the next; so that one operator's judgment might be condemned by another, both objected to by the company, and a suit for damages against the latter by the party sending the message, demonstrate that he agreed with none of them. An operator sending a message might conscientiously believe, and after serious deliberation, become convinced that there was an error in the message, but by assuming the responsibility of an alteration entail considerable annoyance, complication and loss to the party sending the message, who had originally arranged it according to his idea of the requirements of the case.

Cipher messages are in such general use and of such peculiar and varied character that it is often difficult to determine whether a telegram is intended to be construed literally or arbitrarily. It is not remarkable to observe even more peculiar words than "Skiagow," or "Calt" in a telegram, and they may mean Chicago and Salt, or something entirely different; and it appears more reasonable to allow the message to go forward as written, than attempt an alteration which your judgment may deem necessary, when your judgment has no better foundation than appearances.

The relations of a telegraph company with the public are simply that of agents, and the operators hold similar relations towards the company, but not towards the public. The company prescribe certain rules and regulations for the maintenance of their relations with the public, which the latter subscribe to when they send a telegram. The company establish other regulations for the government of an agent which that latter is presumed to agree to upon entering into their service, and also to abide by any other rules so long as he remains in their employ. The company hold the right to remove him for a violation of their rules, and he holds the right to leave their service if these rules are objectionable to his views. The company have no right to question the nature of a telegram which they have accepted for a stipulated consideration, and such being the case, it is hardly reasonable that its agent has a right to exercise his judgment, especially when neither judgment nor common sense is available, since he is necessarily ignorant of the intent and purpose of the sender. It appears to be simply the business of the receiving clerk to understand the *words* contained in a message, irrespective of their apparent sense or signification; the business of the company to forward and deliver such message exactly as the original receiving clerk understands them. There their responsibility ends. If the company are inclined to exhibit a spirit of accommodation towards a customer by having a message repeated, or if the agents of the company have this done in order to satisfy themselves that it has been correctly transmitted, and thus protect the company's business, it appears that operators ought not to question the sense of it, since they are simply employed to work so many hours a day, and the expediency of the matter is immaterial since it does not affect their interests, if the lines are blockaded with messages, to protect the interests of the company. If an operator transmits a message incorrectly, it is caused by carelessness, incompetency, or something else, which the company holds him responsible for; and if he would be willing to accept the same responsibility for the results of his judgment, I see no reason why the company should not accept it, providing they are properly secured. But it is of very questionable utility for a telegraph company to permit any violation of rules which have been adopted under the influences of long experience, and have been so far found to be fully adequate for the purposes intended—namely, the protection of the interests of the company.

SAVANNAH.

OBTAINING FULL DIRECTIONS.

MASSACHUSETTS, June 28, 1872.

To the Editor of the Journal of the Telegraph:

As I have never observed anything in the JOURNAL in regard to this matter, I merely wish to make an enquiry in relation to obtaining full directions from customers, where, and how to deliver their messages.

For instance, A, of Winchester, wishes to communicate the news of a death to B, of Greenfield. After the usual method, he simply directs to "B," Greenfield.

After some delay the operator at Greenfield, ascertains that B lives a mile away. What is to be done. "Oh, very likely, B would be willing to pay any reasonable sum for the delivery of that message," I hear some one say. Perhaps this "B" would be willing, but is every "B" willing?

Out here in the country it is not unusual to receive messages in this way, to be delivered one to three miles away from office, no delivery guaranteed or knowledge of location of "B" connected to the message. Would it not be judicious, at least, for every receiving clerk to obtain full directions about *delivery* of every message? and if "B" lives outside of free delivery, to ask "A" to deposit a sum sufficient to defray the expense of delivery of his message?

CONSTANT READER.

Answer.—Not only would it be judicious, but it is the actual duty of every receiving clerk to require full directions to be upon a message before he accepts it. Also, if the party resides beyond the limit of free delivery, to require that the cost of delivery should be pre-paid, or a sufficient guarantee be given.

TEXAS, June 19, 1872.

To the Editor of the Journal of the Telegraph:

If a receiver at counter cannot change the spelling or wording of a message, please tell us what to do in these cases!

"Send me by express one caike 5 pen neals."

This was handed in by a small white boy, who brought it from his father, living ten miles in the country—said boy could neither read nor write. He wants *one keg five-penny nails.*)

Again:

"Sent emeadtly 2 bunch larch Bannanas, 3 barl. sound Ables."

This handed in by an ignorant colored man, who brought it from a German grocer, away down town.

NOEL.

Answer.—In these cases the chief requisite is common sense. If the receiver *knew* the correct rendering of these messages he should have given it.

NEW CHICAGO, Ks., June 29, 1872.

To the Editor of the Journal of the Telegraph:

I received a message from Indianapolis which requests me to get answer to the same, and send to Kansas City. Now, have I to be responsible for the answer I send? that is if not collected there; or should that message have been pre-paid at Indianapolis?

J. G. MEYERHOEFER, Manager.

Answer.—Indianapolis office is responsible.

To the Editor of the Journal of the Telegraph:

By answering the following, you will oblige.

Are not all railroad operators, who have charge of the business of the W. U. Tel. Co. at their offices, entitled to ten per cent. of the receipts for that Company.

Answer.—The amount to which such operators are entitled, depends entirely upon the agreement made with the Superintendent, when such charge was taken.

ANSWERS TO CORRESPONDENTS.

THERE are eleven words in the following message: "Be down by freight train to-night. Look out to admit us."

JAMES H. WALKER is informed that the "Duplex" system is available only between terminal stations. As yet the principle has been developed only so far as to transmit but *two* messages at the same time.

There is evidently some error regarding the "appointment" matter of which he writes.

THE porous cups in the ordinary blue vitriol battery, if not broken or covered with a deposit of copper, are good for use for any length of time. They should be washed occasionally in water.

The crystalized vitriol which collects on the outside of the jar, as well as that which remains undissolved in the bottom of the jar, is good for use, and should never be thrown away.

The old coppers should be preserved when replaced by new ones, and should be forwarded to the supply office.

To the Editor of the Journal of the Telegraph:

Would you be kind enough to grant me space in your valuable journal to make a suggestion to those whom it may interest. Some time ago my application to become a member of the "Telegraph Life Insurance Association" was rejected on account of physical disability. There are many operators who cannot become members of this Association for the same reason, who have families that would be left quite as destitute, in case they were deprived of their support by death, as the families of the more vigorous and healthful. Such operators, I would ask, if it is not our duty to make provision for our families and those who are dependant upon us for support?

JOURNAL OF THE TELEGRAPH,

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, JULY 15, 1872.

POSTAL TELEGRAPH.

On the 16th of May last, a lengthy debate took place in the United States Senate upon the bill reported by Mr. Ramsay, Chairman of the Senate Committee on Post Offices and Post Roads, known as the "Hubbard" scheme. In commenting upon this debate, we hope to present some facts which may serve to enlighten certain Senators, who, no doubt honestly, yet without a full knowledge of the subject, supported the measure. Prominent among these was the Senator from Maine, Mr. Hamlin, and it is with a portion of his remarks that we take issue, and we trust, that when the truth is plainly shown that the gentlemen we refer to will find reason to change their views, and that henceforth they will be found where both their public and private character would seem to place them, on the side of justice and right.

It appears from the statements of the Senators who participated in the debate, that the consideration of this scheme was brought up at a time when there were but few Senators present and the majority of these were advocates of this specious job. Whether this was a preconcerted trick to pass the bill in the absence of those who have more regard for the rights of private citizens and private property, than they have for the advancement of lobbyists' schemes, and the wholesale spoliation of a vast private estate, for the benefit of a pack of greedy knaves, under the specious, but dishonest, plea of cheapening the rates of telegraphing, we are unable to say, but we are compelled to admit that appearances strongly favor that conclusion.

Some of the Senators, undoubtedly, clearly understood the whole job, and no doubt know into whose pockets the million dollars provided in the bill for merely organizing Hubbard's scheme would go. But there are other Senators who seem to favor this job without understanding what is involved in it, and are thus unwittingly aiding in the consummation of a great swindle on the public and the telegraph companies. Thus, Senator Hamlin, who, to his credit, voted for the appropriation to enable Professor Morse to establish the first line of telegraph between Baltimore and Washington, advocates the "Hubbard" job, under an apparent misconception throughout.

Mr. Hamlin stated in the course of his remarks that, the simple question, in his judgment, was whether it is not wise at this day and this time for our Government to do what almost every other government has done, "take this system of telegraphing operations into its own charge."

Now, as no other government in the world has ever adopted a scheme like this of Hubbard's, and has never sought to seize or control the telegraph, except by honorable purchase, it is evident that Mr. Hamlin does not understand the scheme which he advocates.

There are many other statements contained in Mr. Hamlin's remarks which show that he has not studied the subject upon which he has spoken, and that the statements made to him upon this subject by interested parties are very far from true.

Thus, he says, "When you turn to the European governments, where this system has been taken charge of by govenment, I think we are able to state, in every case successfully, they have reduced rates vastly below anything we have had in this country. In Belgium, for the transmission of ten words, ten cents are charged. In France, from ten to twenty cents. In Great Britain, twenty-five cents. In Canada, twenty-five cents."

Now, in answer to the above, it is a fact that the government telegraphs in Europe have never paid their expenses for a single year since they were established. During the year 1870, the last year for which official returns have been received of the operation of the telegraphs in Europe, the expenses for the operation of the telegraphs exceeded the receipts by over five millions of dollars, and the expenses have exceeded the receipts in Europe, for every year since 1868, by upward of two million dollars per annum.

In regard to the rates, Mr. Hamlin has also been led into error. In Belgium, internal messages, not exceeding twenty words, including address and signature, are sent without guarantee of promptness or accuracy, for ten cents, but upon transit and international messages, twenty cents is the lowest charge. The international messages are those which are sent to other countries, or received from other countries. In either case only one-half of the service is performed by Belgium, that is to say, if an international message is sent from Belgium, the expense of receiving and delivering is not borne by the Belgian administration, nor the expense of transmission of such messages when received in Belgium.

The transit messages are neither sent nor received in Belgium, but are simply shot across the Belgian territory, as a message going from New York to Washington, would be shot through the State of New Jersey; and yet, upon this class of messages, in the transmission and delivering of which the Belgian administration performs no service whatever, they charge double the tariff that they do for their internal messages upon which they perform full service.

In 1870, Belgium transmitted and delivered 1,343,118 internal messages, for which she received 744,641 francs, or a little over eleven cents each. During the same year she transmitted 248,961 and received 258,485 international messages, and 147,848 transit messages, making a total of 655,294 international and transit messages, for which she received 810,048 francs, or about twenty-five cents each. The expense of performing the service was $305,730. The whole number of messages for 1870, counting the internal, both sent and received, and the transit messages, which were neither sent nor received in Belgium, but were simply shot across her territory, amount to 1,998,412, and if these had all been charged at the average internal rate of eleven cents each, the receipts would have amounted to $219,825, or $85,905 less than the expenses.

In France, the telegraph arrangement is very similar to that in Belgium. They have a cheap rate for certain classes of internal messages, and make up their deficiency to a certain extent by a larger tax upon international correspondence. Owing to the disturbed condition of France, resulting from the war with Germany, no report of the working of the telegraph for 1870 has been published. In 1869, the total number of messages sent in France was 4,754,643. The receipts were $1,967,902, and the expenses $2,585,799. The average tolls received upon internal messages was twenty-seven and one-half cents. The average tolls received upon international messages was one dollar and twenty-six cents. Messages of twenty words, including address and signature, may be transmitted from one part of France to another for twenty cents, and between any two stations, situated in the same department, for ten cents. Thus it is possible to transmit messages between the most extreme points in France, a distance of 600 miles, for twenty cents, but a dispatch going from Paris to Brussels, or from Paris to London, costs eighty cents.

But supposing it were true that messages were sent in France for twenty cents, it does not prove anything in favor of governmental telegraphy, since those rates are not self-sustaining, even in that country of cheap labor, but result in a large annual deficit.

In Canada the lines are not under government control, and never have been, and therefore there is no propriety in bringing the telegraph in that country forward as an example in support of any government or semi-government scheme.

Another reason given by Mr. Hamlin, why our Government should take charge of the telegraphic system, is that it operates to diminish the revenue of the Post Office. To show how little weight this view of the case is entitled to receive, it is only necessary to say that if the Government received three cents postage upon each of the ten million of telegrams, annually transmitted in this country, the gross revenue would only be increased $300,000, an

Digitized by Google

insignificant sum out of a total expenditure for the Post Office Department of $25,000,000 per annum. But how the adoption of the "Hubbard" scheme is going to prevent a diminution of the revenues of the Post Office does not appear. By the provisions of the proposed bill, messages are to be deliverd at the expense of the Post Office Department within a mile of every telegraph office. There are now in the United States over six thousand telegraph offices. If the number is not reduced after the "Hubbard" scheme has gone into operation, the Post Office Department will be required to furnish at least one man to deliver messages at each of these offices, while at many of the larger offices a very large force would be required. At New York, for example, it would require at least one hundred and fifty men, for this purpose alone. Supposing, however, that only one man was employed at each of the six thousand offices, at a salary of one dollar per day each, there would be an annual expenditure for this purpose alone of over two million dollars.

For performing this service, besides furnishing office room, stationery, printing, stamps, receiving the messages from customers over the counter, taking charge of, and accounting for the money, furnishing reports and supervising the business generally, the Post Office Department, under this bill, is to receive five cents per message; and if 10,000,000 messages were sent per annum, the total revenue accruing to the Post Office Department, from this source, would amount to just half a million dollars, while the expense of delivering alone would be more than two and a half millions of dollars.

Another reason which Mr. Hamlin adduces why he advocates the "Hubbard" job, is, that the Western Union Company has abrogated the arrangement under which it transmitted Weather Reports for the Signal Office for which, he says he believes, about $250,000 have been paid annually. Now, in the first place, there is no provision in the "Hubbard" bill for the transmission of these Weather Reports at any price. In the second place, the Western Union Company has never refused to transmit them, promptly and accurately, and at a price to be fixed by the Postmaster-General. In the third place, the Western Union Company has never received $250,000 for sending these reports annually, nor has it received one-quarter of that sum of money for transmitting these Weather Reports during the past two years. According to the terms of the agreement, the Signal Office should have paid this Company about $65,000 for transmitting the Weather Reports last year, but they have, thus far, paid only about one-half of the latter sum.

If Mr. Hamlin has been informed by the Signal Office, that they paid this Company $250,000 for transmitting their reports, we suggest that it would be a very proper subject of investigation, with a view of ascertaining what has become of this large sum of money.

It is always a very safe and popular thing to pitch into corporations upon every and all occasions, and the Western Union Telegraph Company cannot expect to escape the shafts of slander which are thrown from envy, self-interest, or any of the other meaner motives which actuate some portions of mankind. The simple truth, however, is, that the Western Union Company has, within the past six years, doubled the extent of its lines and wires; more than doubled the number of its offices, employés, and the number of messages annually transmitted, while it has reduced its tariffs over fifty per cent. With a property thus increased in value and with a business so largely augmented, its net revenue for 1871 was less than in 1866. During the past six years it has only declared three annual dividends, of four per cent. each, and the remainder of its income, together with all of its vast energies, have been devoted to the public good. It is all very well talking about cheapening telegraphing for the people at the expense of somebody else, but when any government, company, or individual, can be named which has done as much toward furnishing cheap telegraphic facilities as the Western Union Company has done, we shall be ready to listen with more patience to their theories.

If Mr. Hamlin thinks that the Western Union Telegraph Company, and the other telegraph companies, of the United States, are not furnishing such facilities as the public require, and at such prices as are fair and equitable, and that the Government can do the business more satisfactorily, then we can conceive that he may regard it as his duty to advocate the establishment of a government-telegraph.

In such a case the Government should buy the lines and work them as best it may for the public good. Contracts already exist between the Government and the telegraph companies, by which the telegraph companies are compelled to sell their lines to the Government whenever the Government elects to take them, at a price to be fixed by five impartial arbitrators, two of which are to be named by the Government, two by the telegraph companies, and the fifth by the other four. With such an easy, simple and just method as this for the Government to acquire the telegraph property of the country at its value, what reason is there for the Government of the United States to negotiate for a partnership arrangement for the establishment of a competitive telegraph system with a professional lobbyist, who has never owned a rod of telegraph line; never had any telegraphic experience, and, to any considerable extent, has never even patronized the telegraph?

JULY 1, 1872, the Western Union Telegraph Company owned:

Miles of Poles	60,668
Miles of Wire	134,395
Number of Offices	4,887
The total number of persons in its service at that date	7,321
The total number of messages transmitted in 1871, was	11,404,653

THE attention of Managers of Offices is directed to the list of towns and villages on Staten Island, given in the Tariff Circular, with the rates of delivery to each, from the Quarantine office. Only recently a customer, in offering a message for New Brighton, Staten Island, at one of our large Western offices, was compelled to leave without sending it, owing to the ignorance of the receiving clerk, who did not conceive it to be within the line of his duty to enquire of New York, (with whom his office was in direct communication), the rates of delivery. Five minutes of time, intelligently applied, would have secured the business to the company, satisfaction to the customer and a little useful knowledge to himself.

IN this issue Buell advertises a new Key to match his "Little Monitor" Sounders.

THE millenium has not yet arrived. This is evident from the fact that in an existence of one short month, the corporation of which Mr. G. B. Hicks is the head, has discovered pirates dealing out spurious wares in their name. See our advertising columns.

THE ARTISAN comes to our table in an enlarged and attractive form. It is pleasing to note these evidences of success. Every advancement of this character indicates a growth of scientific knowledge in the country of which such journals are acknowledged exponents.

NEW YORK, NEWFOUNDLAND AND LONDON TELEGRAPH COMPANY.

AT a late meeting of the Governing Committee of the New York Stock Exchange, a report was received and adopted from the Committee on Stock List, by which the stock of the New York, Newfoundland and London Telegraph Company was ordered to be placed on the free list of stocks at the Exchange. The following is the official statement of the corporation in question:

The official statement of the New York, Newfoundland and London Telegraph Company, incorporated by the Legislature of Newfoundland by Act of April 15, 1854;

Capital stock authorised by act April 15, 1854	$3,000,000
Capital stock authorised by act April 26, 1867	3,000,000
Total	$6,000,000
Of which there as been issued, and the proceeds expended in construction and maintenance of the company's lines, 38,382 shares, of $100 each	3,838,200
Increase of stock, all subscribed for, and issued June 1, 1872	480,000
Total	$4,318,200
Bonded Debt—Five per cent. Bonds, mature June 1, 1874, interest guaranteed by Newfoundland Government	85,000
Total	$4,403,200

No floating debt. Surplus, $81,746. Net earnings for year ending Feb. 1, 1872, in gold, $412,207. Dividends declared from Aug. 1, 1867, to date, average ten per cent. per annum.

Officers—President, Peter Cooper; Vice-President, Cyrus W. Field; Treasurer, Moses Taylor; Secretary, E. T. Hatfield; Superintendent, H. H. Ward.

Directors—Peter Cooper, Moses Taylor, Cyrus W. Field, Marshall O. Roberts, Wilson G. Hunt.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
July 15, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since July 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the JOURNAL *as possible.*

NEW OFFICES.

366 Albin, Iowa.
14 Booth Bay, Me., heretofore an Other Line office.
356 Bellevue, Iowa.
17 Biddeford, Me.
21 Bay View, Mass.
446 Bolckow, Mo.
196 Barnett, Ga.
28 Deerfield Mass.
21 Danvers, Mass.
483 Dallas, Texas.
46 Dutchess Junc., N. Y., ck. Fishkill, N. Y., heretofore an Other Line Office.
29 Edgecomb House, Groton, Conn., ck. New London, Conn.
40 East Canaan, Conn.
25 East Douglass, Mass.
21 Essex, Mass.
241 Emerald, O.
146 Green Pond, S. C.
25 Greene, R. I.
329 Harrisburg, Ill.
232 Houston, O.
151 Hazelwood, Pa., tariff same as and ck. Pittsburgh, Pa.
17 Kittery, Me.
11 Lincolnville, Me.
308 Milford, Ill.
347 Mapleton, Ill.
140 Petrolia City, Pa.
21 Peabody, Mass.
455 Pickering, Mo.
478 Reams Stock Yards, Ind. Terr.
28 Shirley, Mass.
11 Stockton, Me., heretofore an Other Line office.
11 Searsport, Me., heretofore an Other Line office.
Stoner Station, Idaho, tariff same as Snake River, Idaho
25 Southbridge, Mass.
61 Sewall's Point, Va., Summer Office.
329 Tunnel, Ill.
35 West Charlotte, Vt.
206 Washington, Ga.
17 York, Me.

SUMMER OFFICES RE-OPENED.

* Deal, N. J.
133 Hot Springs, Va.
33 Healing Springs, Va.
39 Lake George, N. Y.
41 Norwood, N. J.
143 Old Sweet Springs, W. Va.
142 Rockbridge Alum Springs, Va.
142 Rockbridge Baths, Va.
143 Sweet Chalybeate Sp'gs, Va.
18 Tiverton, R. I.
Watch Hill, R. I., 15 cents more than Stonington, Conn.
133 Warm Springs, Va.

OFFICES CLOSED.

Douglass, Texas; Locke, N. Y.; Phillipsburg, Clarion Co., Pa.; Snake River, Idaho; South Canadian, Ind. Terr., and Vermillionville, La.

GENERAL INFORMATION.

The following is a revised list of offices on the Alabama and Chattanooga Line, with "tariff for Other Lines," from Chattanooga, Tenn.:

Attalla, Ala.,	50	3	Chattanooga, Tenn.
Carthage, Ala.,	90	6	"
Collinsville, Ala.,	50	3	"
Birmingham, Ala.,	75	5	"
Eutaw, Ala.,	90	6	"
Green Pond, Ala.,	75	5	"
Livingston, Ala.,	100	7	"
Morgansville, Ga.,	25	2	"
Springville, Ala.,	60	4	"
Trenton, Ga.,	25	2	"
Toomsuba, Miss.,	100	7	"
Valley Head, Ala.,	30	2	"

Messages for the following points on Staten Island may be taken and sent to Quarantine, S. I., from which office they will be delivered at charges here given:

	Charges for Delivery.		*Charges for Delivery.*
Castleton Heights,	$0.50	New Dorp,	$1.00
Clifton,	0.50	Port Richmond,	0.75
Elm Park,	1.00	Pleasant Plains,	1.00
Factoryville,	0.50	Princess Bay,	1.00
Fort Wadsworth,	0.50	Richmond Valley,	0.50
Garrett's Sons Station,	1.00	Rossville,	1.25
Gifford's Station,	1.00	Sailors' Snug Harbor,	0.50
Hugenot Station,	1.00	Stapleton,	0.25
Mariners' Harbor,	1.00	Tottenville,	1.00
New Brighton,	0.25	Vanderbilt Landing,	0.25

On and after August 1, 1872, the "tariff for Other Lines" to Tracey City and Sewanee, Tenn., will be 50 and 3 from Cowan, Tenn.

Business for Rising Sun and Patriot, Ind., "offices on Other Lines," will hereafter be transferred at Aurora, Ind., instead of Lawrenceburg as heretofore, ck. Aurora, Ind.

The name of the office heretofore known as Steamboat, Pa., has been changed to Glen Loch, Pa.

The office at 347 Norris, Ill., is in Fulton Co.

WILLIAM ORTON, President.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 17. NEW YORK, AUGUST 1, 1872. WHOLE NO. 114.

THE DIFFERENTIAL GALVANOMETER.

The differential galvanometer invented by M. Becquerel, is one of the most useful and convenient instruments for making electrical measurements which has ever been devised, and is probably destined to be much more extensively used in the telegraph offices in this country than any other form of galvanometer. As in the sine and tangent galvanometer, the needle is poised upon a pivot, or suspended by a silk fiber, but instead of being surrounded with a coil composed of the convolutions of a single wire, as in those instruments, it is surrounded by a coil formed of two wires exactly equal in length, size and conductivity, wound simultaneously round the frame, and similarly situated in respect to the needle, so that when opposite and equal currents are sent through each of the wires the needle remains at zero, the current which passes through one wire exactly neutralizing the effect of that which passes through the other. If the current which passes through one-half of the coil is stronger than that which passes through the other the balance will be destroyed, and the needle will be deflected by the stronger current with a force equal to the difference in the strength of the two currents.

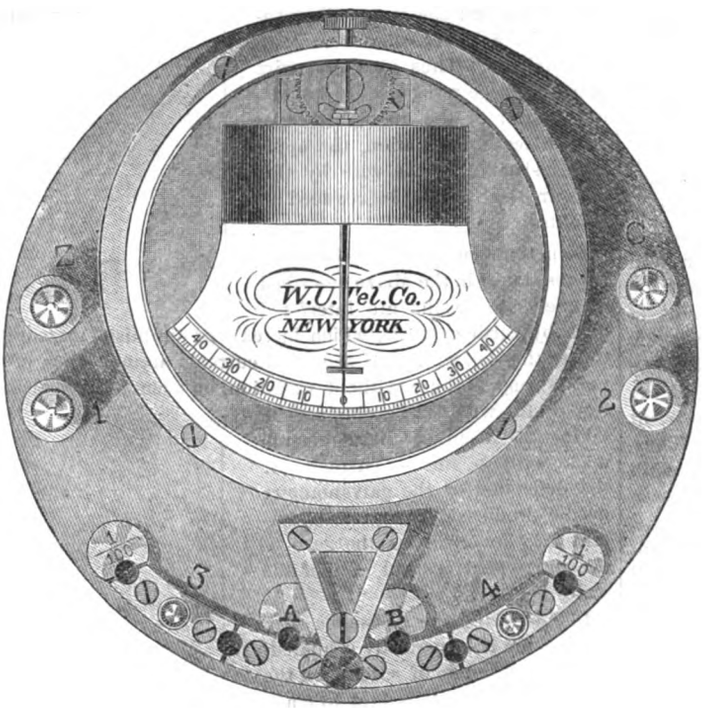

FIGURE 1.

As the strength of an electric current from a given battery upon similar wires is inversely proportional to their length, if the current from a battery is divided between two such wires of unequal length, each connected to one of the wires of the coil, the shorter wire will receive a greater portion of the current than the longer one, and the stronger current in the shorter wire will overcome the current in the longer wire and deflect the needle. The extent of the deflection will be proportional to the difference in the length or conductivity of the two wires, and the direction of the deflection will indicate which of the two wires is the longest.

Figure 1 represents a double shunt differential galvanometer, manufactured by the Western Union Telegraph Company for the use of its employees. The two wires forming the coil which surrounds the needle are indicated by two circular parallel lines, one circuit extending from 4 to B, and the other from 3 to A. These wires have similar resistances, and are situated alike respecting the needle, so that when a battery is connected so as to divide its current between the two halves of the coil, no visible effect is produced upon the needle, the current from 3 to A tending to deflect the needle to the left, while that from B to 4 tends to deflect it to the right; and since both forces are equal, the needle remains in a state of equilibrium. The instrument is provided with two shunts, one for each half of the coil of the galvanometer, so that either one or both halves of the coil may be shunted as desired. Each shunt consists of a comparatively short wire, and has a resistance of $\frac{1}{99}$ of each half of the coil, so that when thrown into the circuit by the insertion of the peg $\frac{99}{100}$ of the current passes through the shunt, and only $\frac{1}{100}$ through the half of the coil of the galvanometer.

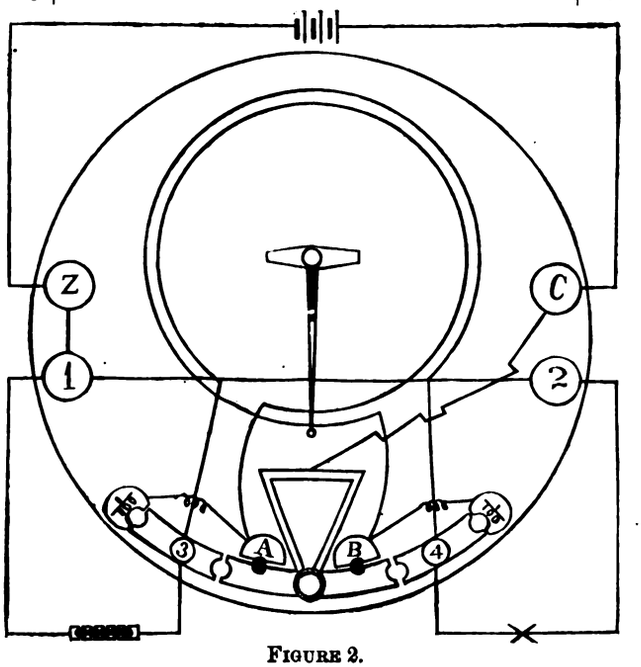

FIGURE 2.

In measuring the resistance of a relay, sounder, wire or any other conductor, both ends of which are at hand, the connections should be made as in the diagram (figure 2).

The positive pole of the battery is connected with the thumbscrew C, and the negative pole with Z; one terminus of the rheostat, or resistance coils, with 3, and the other terminus with 1. The terminals of the wire or helices to be measured are connected with 4 and 2, and pegs inserted at A and B. Resistances are then to be inserted between 1 and 3, by removing the pegs from the resistance coils until the resistance in circuit 1 and 3 equals the resistance in 2 and 4. When the two resistances are precisely the same, and the key is depressed, the needle points to zero of the scale. If the resistance of the wire or helices which are being measured is greater than the rheostat, the current in circuit 1 and 3 will be stronger than that in 2 and 4, and the needle will be deflected to the left. If the resistance of the wire or helices is less than that of the rheostat, the current in circuit 2 and 4 will be stronger than that in 1 and 3, and the needle will be deflected to the right. When the needle is not deflected at all on the depression of the key, the resistances of the two circuits are equal, and the sum of the resistances inserted by the removal of the pegs in the rheostat, is equal to the resistance of the wire or helices which are being measured.

The resistance coils of the rheostat which accompanies the differential galvanometer contain respectively 1, 2, 3, 4, 10, 20, 30, 40, 100, 200, 300, 400, 1,000, 2,000, 3,000 and 4,000 ohms, the sum of which is 11,110 ohms, which is the limit of measurement by the above plan. When higher resistances are to be measured, a peg should be inserted in the orifice between the metallic bar 3 and the disc marked $\frac{1}{100}$, the other connections remaining as before. T

Digitized by Google

portion of the current which traverses the circuit from C to 1 through the rheostat will now be divided into two parts, $\frac{99}{100}$ traversing the shunt, and $\frac{1}{100}$ traversing one-half of the coil of the galvanometer. As only $\frac{1}{100}$ of that portion of the current which passes from C to 1 goes through one of the wires of the galvanometer, while the whole of that portion passing from C to 2 passes through the other wire of the galvanometer, it is necessary, in order to produce equal effects upon the needle and to maintain its equilibrium, that the current in the circuit extending from C to 1 should be one hundred times stronger than in that from C to 2. This is effected by making the resistance of the rheostat one hundred times less than that of the wire, helices or other conductor which is being measured. The resistance of the coils which are inserted by removing the pegs from the rheostat must then be multiplied by one hundred in order to get the actual resistance of the conductor. Resistances as high as a million ohms can be measured by this method.

For measuring resistances of less than an ohm, the connections should be substantially the same as in figure 2. Care should be taken, however, to use short and thick copper wires for connecting the rheostat with terminals 1 and 3, so that there may be no appreciable resistance added by the connecting wires. A peg should be inserted in the orifice between the metallic bar 4 and the disc marked $\frac{1}{100}$, so as to introduce the shunt in the circuit containing the short wire to be measured. When the needle remains at zero, on depressing the key, the resistance of the wire will be $\frac{1}{100}$ of the amount which has been inserted in the other circuit by the removal of the pegs in the rheostat. Thus, if a piece of No. 8 iron wire $26\frac{4}{10}$ feet in length (one two-hundredths of a mile) be inserted between 4 and 2, a peg being inserted at orifice marked $\frac{1}{100}$, and it requires 6 ohms to be unplugged in the rheostat to balance the needle, then the $26\frac{4}{10}$ feet of wire will have a resistanee of $\frac{6}{100}$ of an ohm, and a mile of such wire would have a resistance of $200 \times \frac{6}{100} = 12$ ohms.

In measuring line resistances exceeding one megohm, [1,000,000 ohms] the following plan may be used: Connect the line to 4, and the positive pole of the battery to 3, the negative pole being grounded; insert pegs at A and B, and observe the deflection, which should not exceed 40. Remove the line wire and insert one end of a resistance coil whose opposite end is grounded. Shunt the galvanometer by inserting plugs on both sides, and reduce the number of cells in the battery to one-tenth of the original number. Then vary the resistance coils so as to reproduce the same deflection as before, by causing the same quantity of electricity to pass through the galvanometer, and the resistance of the line will be found by multiplying the number of ohms unplugged in the rheostat, by 100×10, or one thousand, the joint diminution of the current passing through the coil of the galvanometer by the shunts and the reduction of the battery.

In testing a telegraph wire for resistance to conductivity, when the atmosphere is dry and there is no escape of the current or mixture with those on parallel lines, the connections should be made as in the following diagram (figure 3). The positive pole of the battery is connected to thumbscrew C, and the negative pole grounded. A ground wire is attached to thumbscrew Z, which is connected by a wire with 1. One end ot the rheostat is connected with 3, and the other end with 1. One end of the wire to be measured is connected with thumbscrew 4, and the distant end is grounded. When pegs are removed from the rheostat until the needle of the galvanometer remains at zero unaffected by the closing of the key, the resistance of the wire will be equal to the resistance unplugged in the rheostat. To ascertain the mileage resistance of the wire, its total resistance must be divided by its length in miles. Thus, if the total resistance of the wire is 4,000 ohms, and its length 250 miles, the mileage resistance will be $4,000 \div 250 = 16$ ohms.

In testing for resistance to conductivity in this manner, care must be taken to ascertain whether there is any escape of the current, or mixture with other currents, arising from imperfect insulation, for if there is the resistance of the circuit will be diminished and the wire will apparently be a better conductor than it actually is. Thus, if upon a wire whose mileage resistance is 16 ohms, one-quarter of the current escapes from defective insulation, the apparent resistance of the wire by this measurement would be reduced to 12 ohms.

Sometimes, when a wire is tested for resistance in the above described manner, the results are interfered with by earth currents, which increase or diminish the testing current. If the earth currents are not very strong, and are without variation, an accurate test of the wire can be obtained by taking the mean of measurements made with + and − currents, or the deflection of the galvanometer needle produced by the earth current may be taken as the zero of the instrument instead of 0 of the scale.

In measuring the resistance of a wire which is imperfectly insulated, or where it is one of several on the same set of poles, it is best to make a loop by connecting it at the distant station without ground with another extending between the same places. The termini of the loop are then connected with the galvanometer in the same manner as the termini of a helix, as illustrated in figure 2. The ground wire is removed from the battery, and the negative pole connected with thumbscrew Z.

The mileage resistance is obtained by dividing the total resistance of the loop by the number of miles of wire which is embraced in it. Unless there is an escape upon both wires used in forming the loop, this method will give reliable results. If there are three or more wires running to the distant station, the measurement can be made with still more accuracy by the following method: After one loop has been tested, substitute a third wire in place of the second in the loop, and make another test; and then substitute the second wire in place of the first, and test again. Thus, for example, if the resistance to conduction of wires Nos. 1, 2 and 3 is wanted, connect at the distant station first Nos. 1 and 2, and measure the resistance of the loop so formed. Then connect Nos. 1 and 3, and measure the loop embracing those wires. Then connect Nos. 2 and 3, and measure their resistance. The resistance of each of the three conductors can then readily be obtained from these figures. Thus, suppose that Nos. 1 and 2 looped together measure 6,000 ohms, Nos. 1 and 3 measure 7,000 ohms, and Nos. 2 and 3 measure 8,000 ohms. By adding together the resistance of the first two loops, and substracting the resistance of the third, and dividing the remainder by 2, the resistance of No. 1 is found to be 2,500 ohms. [6,000 + 7,000 − 13,000 − 8,000 − 5,000 ÷ 2 = 2,500.] Subtracting this from 6,000, the resistance of No. 2 wire is found to be 3,500, and subtracting the latter amount from 8,000, gives 4,500 ohms as the resistance of No. 3.

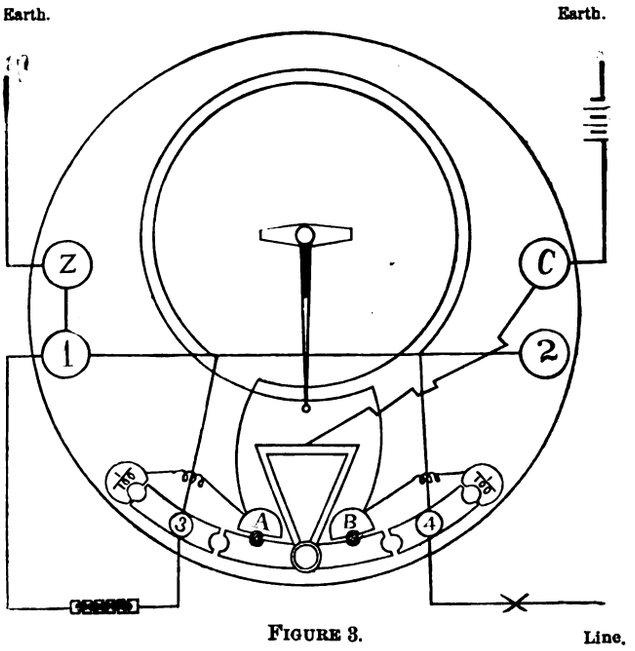

FIGURE 3.

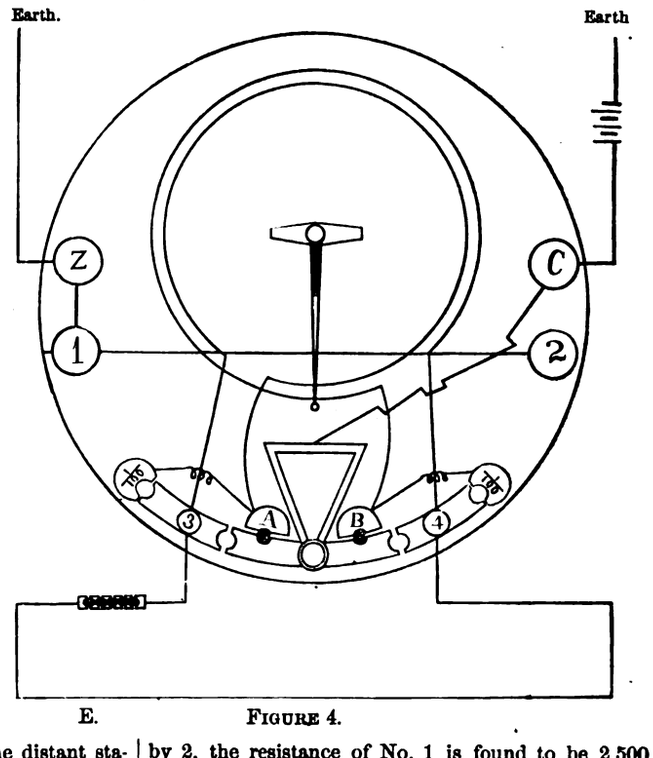

FIGURE 4.

The advantages arising from this mode of testing are that all interferences from extraneous currents and inaccuracies due to imperfect ground wires, as well as to escapes and earth currents, are avoided. In measuring the insulating resistance of a wire, the mode employed is similar to that illustrated in figure 3 for measuring its resistance to conductivity, except that in measuring the resistance of the insulation

Digitized by Google

the distant end of the wire is insulated or disconnected from the earth. In making this measurement, however, the resistance of the wire should be carefully obtained, because a wire of great resistance due to imperfect joints, or the presence of many helices of long, fine wire, would apparently increase the resistance of the insulation.

To obtain the mileage resistance of insulation of a wire, its total insulating resistance must be multiplied by the length of the wire in miles. Thus, if the insulating resistance of a wire which is three hundred miles long is 6,000 ohms, its mileage resistance would be 1,800,000 ohms, because the loss of current by escape would be three hundred times greater upon the whole line than upon a single mile.

Daily measurements of all the principal circuits ought to be made and recorded for comparison, so that any fault, however trivial, may be at once detected and removed. Every wire should be so well insulated as not to measure less than one million ohms per mile, although this standard of excellence is rarely ever attained in very rainy weather in any country. In England, some of the best lines show an insulating resistance in damp weather of less than one hundred thousand ohms per mile. Of course, such low insulation as this would not admit of practical working, except upon lines of comparatively short extent, or where a very large conductor was used. Mr. Culley, the Engineer in Chief of the English Post Office Telegraphs, states that the insulation per mile, on two wires extending between Dublin and Belfast, was reduced from 78,750,000 ohms per mile, in fine weather, to 131,300 ohms per mile during a rain, and yet that the lines worked well. The secret of their working was the shortness of the lines, 126 miles, and the large wires, Nos. 4 and 8 gauge. The successful working of a wire depends upon the proportion of the entering current which reaches the distant end. Calling the current upon the line, near the battery, the entering current, and that at the distant end of the line, near where it enters the ground, the arriving current, then the distance to which any given fraction of the entering current will reach, is directly proportionate to the square root of the conductivity of the wire, to the square root of the insulation. In the above mentioned case a sufficient quantity of the entering current would arrive at the distant station to work the instruments well. But suppose the line were thrice as long, and the mileage insulation the same, the fraction of the entering current which would arrive at the distant end would not be sufficient to work the apparatus. Long lines therefore require better insulation than short ones.

Figure 4 represents the connections to be made with the differential galvanometer when locating the distance of a ground connection by the loop test. Connect the wire to be tested for the fault with a good wire at the distant station, and the defective wire to one end of the rheostat, the other end of which is attached to thumbscrew 3. Connect the good wire to thumbscrew 4, the positive pole of the battery to C, and ground the negative pole. When the key is depressed the current will enter the two wires through the termini of the loop and return through the connection with the earth at E; and as the distance between the rheostat and the ground contact at E is less than that between 4 and E, the current between 3 and E will be stronger than in 4 and E, and the needle will be moved to the left. Resistance must now be added to 3 and E, by removing the pegs in the rheostat until the needle is balanced, when the resistance in 3 and E will equal that of 4 and E. Subtract this resistance from the total resistance of the loop, when the wires which compose it are in good order, and divide the remainder by 2 and the quotient will be the resistance of the defective wire between the testing station and the fault.

For example, suppose the resistance of the loop to be 500 ohms, and that it requires 100 ohms to be unplugged in the rheostat to bring the needle to zero, then $\frac{500-100}{2} = 200$ ohms, the resistance of the faulty wire between the station tested from and the escape.

Let 4 E — x and 3 E — y.

Then x+y—L, the resistance of the loop.. R, the resistance unplugged in the rheostat, + y — x, or 3 R E—4 E, therefore $y = \frac{L-R}{2} = 500-100+2-200$

Suppose that the loop measuring 500 ohms resistance contains 60 miles of wire, then, as the faulty wire measures 200 ohms, we have, by proportion, 24 miles as the distance of the fault from the testing station.

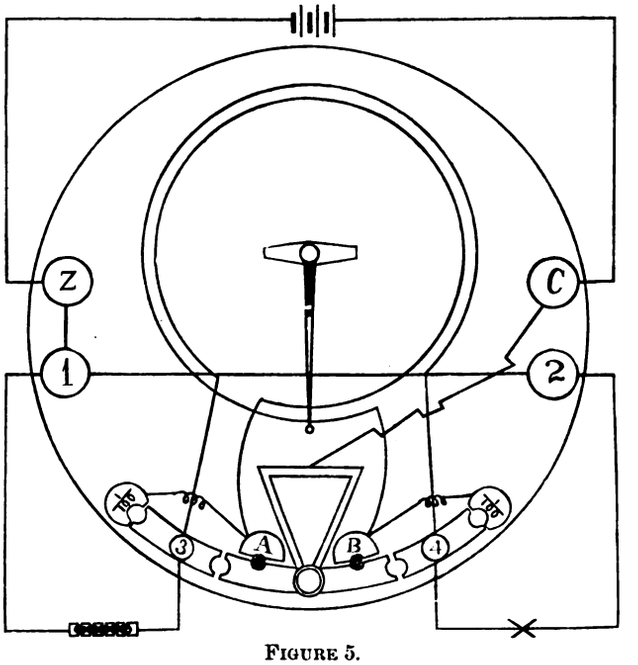

FIGURE 5.

$500 : 60 :: 200 : 24$, or $\frac{60 \times 200}{500} = 24$.

In case the resistance of the loop is not known, it can be found by following the directions previously given, and connecting the wires as illustrated in figure 5.

When a second wire cannot be obtained for making the loop test, the following method may be used for determining the location of a fault:

Ascertain the resistance of the wire before the fault appeared, and call this L; the resistance of the wire when put to earth at the distant end, after the fault has been developed, and call this P; and the resistance of the wire when disconnected from the earth at the distant end, and call this R. Multiply P by P, and R by L, and add the products together; subtract from this sum the product of R multiplied by P, and also that of L multiplied by P, and deduct the square root of the remainder from P. The remainder will give the resistance of the wire between the station tested at and the fault.

Suppose, for example, that the wire has a resistance of three hundred ohms, and the escape of two hundred and eighty-eight ohms, and that the latter is situated at a distance of two hundred and four ohms from the testing station.

$$L = x + y = 204 + 96 = 300.$$

$$P = x + \frac{y \times z}{y + z} = 204 + \frac{96 \times 288}{96 + 288} = 276.$$

$$R = x + z = 204 + 288 = 492.$$

$$\left.\begin{array}{l} P \times P = 276 \times 276 = 76.176 \\ R \times L = 492 \times 300 = 147.600 \end{array}\right\} 223.776.$$

$$\left.\begin{array}{l} R \times P = 492 \times 276 = 135.792 \\ L \times P = 300 \times 276 = 82.800 \end{array}\right\} \frac{218.592.}{5.184.}$$

Deducting the square root of 5.184 from P (276—72 — 204), we have 204 ohms as the distance of the escape from the testing station.

For measuring the internal resistance of a battery with the differential galvanometer, the following method is employed: Connect the positive pole of the battery with C, and the negative with 3, inserting a plug at A, and also in the orifice marked $\frac{1}{100}$ on the left hand side of the galvanometer. When the key is depressed only $\frac{1}{100}$ of the battery current will flow through one-half of the galvanometer coil, $\frac{99}{100}$ passing through the shunt. The deflection of the needle must be noted. Now, connect the positive pole of the battery with thumbscrew 4, and the negative pole with one end of the rheostat, the other end of which attach to the thumbscrew 3. Insert plugs at both shunts and at A and B. The portion of the current which flows through the galvanometer now passes through both halves of the coil, and the deflection of the needle is consequently increased. Now remove the pegs from the resistance coil until the deflection of the needle is the same as it was when the current passed only through one-half of the coil, and the resistances unplugged will be equal to the resistance of the battery.

ELECTRIC MANIFESTATIONS OF VOLCANIC ERUPTIONS.—Professor Palmieri records a singular observation on the recent remarkable eruption of Mount Vesuvius. The vaporous emanations alone were observed to be charged with positive electricity, while the ashes alone were charged with negative electricity. Hence electric effects resulted from the collision of the clouds of ashes with those of vapor, thunder and lightning being produced as in an ordinary storm.

A NEW and powerful thermo-electric battery has been invented by Noë, of Vienna. The alloys used are as yet kept secret. It is stated that ten of the elements of the battery are equal to one Daniell cell, and twenty equal one Bunsen cell. Seventy-two elements arranged for intensity decompose water rapidly, two series of thirty-six each operate a Ruhmkorff coil, and four series of eighteen produce powerful electro-magnets. If all that is said of it be true, we have at last arrived at the time when electricity may be turned on like steam, water, gas, or any other agent in common use.

MR. RICHARD A. PROCTOR, in the *Mechanic's Magazine*, seems quite inclined to favor the hypothesist that many, if not all meteorites, are derived from the discharge of matter from the sun, and states that, however strange and startling this idea may be at first sight, it cannot be condemned as illusory. He suggests that the solar prominences may result from the shooting forth of liquid or solid masses, or streams of matter, and that what we know as meteorites may have been propelled from beneath the surface of the sun.

Mr. Runyard follows in the same vein, and thinks that even if meteorites are not composed of ejected masses, they may be formed by the aggregation of metallic vapors emitted from the sun or other stars.

FOREIGN TELEGRAPHIC ITEMS

THE directors of the China Submarine Telegraph Company have declared a further interim dividend of 3s. per share on account of the profits for the year ending June 30, 1872. The directors of the British Indian Telegraph Company have declared an interim dividend of 6s. per share on account of profits for the year ending December 31, 1871.

THE receipts of the Great Northern Telegraph for June, was 214,796fr. (£8,595), against 138,390fr. (£5,536) in 1871, showing an increase of 76,400fr. (£3,056). In the corresponding month of June, last year, only the Hongkong-Shanghai section of the China cables was open.

THE Indo-European Telegraph Company have at last reduced their tariff, but still not to such an extent as to lead to the use of their line for family communications.

IT is officially notified that the Telegraph Construction and Maintenance Company (Limited) have successfully repaired the Brest end of the French Atlantic Telegraph Company's main cable. The Maintenance ship Robert Lowe was employed for the purpose, and Captain Halpin had charge of the expedition. The necessity for this repair was referred to in the directors' report to the general meeting of the 6th March last.

BRITISH AUSTRALIAN TELEGRAPH.—Full powers have been granted to the directors for raising the capital required for a cable from Port Darwin to the Norman River in Queensland, at such time and in such manner as they may determine. This extension is to be made in compliance with the wish of the Queensland Government. With regard to the interruption of the cable between Java and Port Darwin, we learn that the Telegraph Construction and Maintenance Company are under contract to repair the cable at their own expense.

POST OFFICE TELEGRAPHS.—The total number of messages forwarded from Postal Telegraph Stations tions in the United Kingdom during the week ending the 6th July, 1872, and during the corresponding week of 1871: Week ending July 6th, 1872, 294,496; week ending July 8th, 1871, 241,726; increase in the week of 1872, on that of 1871, 52,770.

THE GERMAN TELEGRAPHS.

The administration of the German Telegraphs has just published the annual statistical returns of the department for 1871, from which we perceive that there was a considerable augmentation of the traffic, as compared with the previous years. At the close of last year there were ninety-nine branch establishments—of which twenty are at Berlin alone— and 1,093 telegraph stations. The largest number of telegrams, 3,806,187, passed through the offices at Berlin—the receipts from which amounted to 542,558 thalers; the second on the list if Frankfort, with 1,996,275 telegrams, producing 241,589 thalers; then follows Cologne, with 1,509,505 telegrams and 157,322 thalers receipts; Hamburg stands fourth on the list with respect to the number of telegrams, 1,091,153, but second only to Berlin as regards the amount received, 314,504 thalers; Breslau comes next with 721,079 messages and 64,599 thalers; and then Dresden, 714,213 telegrams and 51,596 thalers; Halle-on-the-Saal, 540,496 telegrams and 11,988 thalers; Hanover, 503,018 telegrams and 28,923 thalers; Leipzig, 485.605 telegrams and 70,161 thalers; and Stettin, 434,967 telegrams and 59,580 thalers; then follow Bremen, Konigsburg, Magdeburg, Coblenz, Munich, Stuttgart, Carlsrund, etc. The total number of messages sent off was 5,213,837 to places in Germany, against 4,731,919 in 1870, and 1,184,752 to foreign countries, against 958,913 in 1870.

THE TELEGRAPH IN SAN SALVADOR, C. A.

The Republic of Salvador has now about 500 miles of telegraph wire in operation.

The Government is building another line of 50 miles, a second line between San Vincente and Chicameca.

REMARKABLE ELECTRICAL INSTRUMENTS.

At a recent meeting of the Society of Telegraph Engineers in London, first and foremost among the objects of interest was Lord Lindsay's giant electro magnet, by far the largest in the world. It stood in the corner of the largest room, and consists of several straight massive horizontal bars of soft iron, running upon wheels, and so arranged as to form a rectangle; the opening between the poles is narrow, only a few inches. Lord Lindsay had to jump over the bars to get into the open square space in the center, and observers stood outside watching his experiments. The magnet consists of more than 26 ft. of iron, each bar having a sectional area of about 36 inches; we were told, says the *Engineer*, that it weighs about six tons, and has fourteen geographical miles of conducting wire wound around it, the coils being then protected by outer casings of wood. It was charged by means of a powerful battery, but as the Grove's battery used for the purpose is not yet completed, only one-fifth the power of the magnet was, according to Mr. Varley's estimate, developed at the *soirée*. Under these conditions, a plate of copper fell between the poles, at the rate, as nearly as we could judge, of ⅛ inch per second, this slow fall through the air being due to the mysterious action of the magnetic rays upon the electrical currents which those rays induced in the copper plate. One experiment which particularly attracted the attention of the observers, was that of inserting a lighted taper between its poles, where it burnt freely so long as the magnet was charged, but directly the current was broken and the magnetism disappeared, the taper was extinguished.

The induced current produced in the wire by the cessation of the magnetism when the battery current is removed, is so powerful that the shock would probably be fatal to any person who by an unfortunate accident happened to complete the circuit at the time. To guard against this, a very elaborate current reverser has been constructed by Messrs. O. & F. H. Varley, which breaks the circuit gradually by introducing resistances varying from nothing up to infinity. The magnet itself was designed by Mr. C. F. Varley. The conducting wire weighs about 600 lb. to the geographical mile, and is nearly a ¼ inch in thickness. We are told that the battery ultimately to be used with this magnet will consist of 150 of Grove's nitric acid cells, each platinum plate of which will expose a square yard of surface, both sides of the plate included. A battery of this colossal size has never before been constructed, nor indeed at all approached in dimensions.

All the bars of the magnet, as already stated, run upon wheels, and the front bars are governed by a screw motion, so as to accurately adjust the distance between the poles.

In the course of the evening Mr. Ladd froze some mercury, and the solidified metal was allowed to fall between the poles to see what diamagnetic effects would result. There were none at all so far as we could see. Most of the observers had taken the precaution of giving their watches into the charge of attendants, lest their good time-keeping qualities should be destroyed by the action of the magnet upon the steel springs.

Another chief object of interest was Sir William Thompson's siphon galvanometer. The apparatus is now in practical use for the reception of messages through the Indian cables, and it is a good instrument for registering indications produced by feeble electrical currents.

Mr. C. F. Varley exhibited a battery, very useful for testing purposes where high potency combined with extreme uniformity from day to day is of vital importance. He exhibited 1,000 of these cells, as well as a number of condensers invented by him to enable long submarine cables to be worked rapidly and continuously. The sheets of tin foil in these condensers are so completely insulated that when they were charged with 1,000 cells and left for three months, at the end of that time, enough of the charge remained to give a brilliant spark. At the *soirée* he discharged the condensers through a sewing needle; the steel was blown into vapor and molten globules, with a loud report and a bright flash of light; some of the globules were blown to the further end of the room. Fine platinium wire was in like manner blown into vapor, but not into globules.

Mr. Apps, the optician, exhibited a very beautiful Gassiot cascade made by him for Lord Lindsay; the electrical stream passed over the edges of a vase made of uranium glass placed under the receiver of an air pump. He also exhibited a vacuum tube twisted into very large letters, constructed of uranium glass, and exhausted to a high degree so that only ⅛ inch spark was required to illuminate it; this was proved by allowing the spark to pass in air between the terminals of the coil. Mr. Apps also had on view several of his patent induction coils; one of them gave a spark 6 inches in length, though of the size only, he states, of an ordinary coil giving a spark of 1½ inch. One of the most useful instruments he had on view was De Wilde's electrical probe and forceps, as used in H. M's military hospitals and by the Prussians during the late war. The principle of the probe is that it carries within it two wires connected with the opposite poles of a weak battery; a current cannot pass till the ends of the wires at the extremity of the probe touch the bullet; the circuit is then completed, and by an electro-magnetic effect the existence and position of the bullet are made known to the operator. The apparatus is intended to make bullet extraction as easy an operation as possible, attended by the minimum of pain to the sufferer. Among the other things which Mr. Apps exhibited were tubes containing sulphate of strontium and sulphate of barium, which remained phosphorescent many minutes after the cessation of the spark; and an improved Wheatstone's bridge arrangement, giving a scale of differences from 1,000 to 1; there was also included a small ivory disk arrangement for reading off approximately very small resistances, to one millionth of an ohm.

Lord Lindsay exhibited among other things a large induction coil, which gave sparks 20 inches long; this coil was made for him by Messrs. O. & H. Varley. The last mentioned manufacturers exhibited a vacuum tube 9 ft. long, which was brilliantly illuminated. They also exhibited a pencil writing Morse instrument, for which they claimed more cleanliness, and a higher rate of speed than with an ink writer; and among their instruments was one of the vacuum lightning protectors for submarine cables, used to prevent lightning, which may strike the land wire, getting into any cable connected therewith.

CORRESPONDENCE.

FOLLOWING COPY.

BUFFALO, July 24, 1872.

To the Editor of the Journal of the Telegraph:

The communication of "Savannah," in your issue of July 15th, calls for a reply, inasmuch as the writer of that article asserts that there appears a lack of definition as to the intent of an assumption made by myself, calling forth "Savannah's" reply. What I *then* said I repeat. An operator who will send "Skiagow," when he *knows* it should be *Chicago*, is guilty of unmitigated carelessness. And yet operators *have* sent it so, not because they thought it was according to rules, but merely to gratify a propensity for the ridiculous and nonsensical. What "Savannah" says about "obedience to rules," the relations of the "Company to the public," and those of "operators to their employers," is, perhaps, just as patent to me as it is to him; and, it seems to me, a mistaken inference which leads any one to suppose I argued in this respect contrary to what he does. It may be asked, "How do you *know?*" or, as "Savannah" claims, "certainty is impossible." Let me illustrate. An office receives a message for Smith or Jones, asking the rate of freight, Buffalo to Chicago. The reply reads, "Coal, ten shillings, Bufalow Skiagow." To send this message, as it was intended to have been written, is not guess-work, but a practical application of common sense. Blunders on the part of writers of messages are common in this region, and I maintain that an operator should send and receive not blindly, without regard to sense or propriety, but *understandingly*. It stands to reason that none but intelligent persons are in the habit of using cipher words, and a person of average ability will discover at once whether a message is cipher, or otherwise. As I said before, cipher messages must not be altered under any circumstances whatever, but a person who, through ignorance, misspells a word, thus placing it beyond the hope of comprehension in its intended sense and significance, will, instead of sueing the Company for damages, be much obliged to you for a correction of his copy. This has been my experience universally.

It is, unquestionably, the duty of receiving clerks to re-write the misspelt words, but numbers of them fail to do so. If operators will keep their eyes and ears open, become familiar with the run of business, especially in those offices where a certain and distinct class of business predominates (it may be that I had particular refference to this class), many ludicrous and some disastrous blunders will be avoided. Let us have a moderate exercise of the intellectual faculties, and less of the automatic. I choose to think that telegraphers, as a class, run higher in the scale than mere machines. Perhaps it is the special privilege of boatmen, and such, to massacre and annihilate "the King's English;" and, perhaps, also, my friend "Savannah" has not had the delectable (?) experience of deciphering one of their communications, otherwise he would think as I do in the matter of their writing, which is, that there can be but one opinion about it, and that to send some of their messages verbatum would produce chaos itself.

BUFFALO.

ATHENS, PA., July 24, 1872.

To the Editor of the Journal of the Telegraph:

Noticing an article, signed "Buffalo," in your issue of June 15th, which so nearly concurs with my own views upon the subject he so ably discusses, I feel a desire to contribute just a word on the same. Some years experience have fully convinced me that "Buffalo" knows "whereof he affirms," and that numberless "bulls" are the result of this very "habit or rule" (as he styles it) of "following copy." Also, that a too rigid adherance in some respects, and *great* negligence in others, on the part of operators to obey Rule 24, is, in a great degree, detrimental to the interests of the Company. I, for one, cannot understand, nor do not believe, that Rule 24 is intended to convey the idea that operators should necessarily transmit a word or words "as written," when he or they may chance to know that, if so transmitted, the meaning of such words will indicate something entirely different from that desired by the sender, and also cause the receiver to think there has been a mistake in the transmission. Yet it is an every day occurrence that operators are found interrupting the business of the whole line in the endeavor to settle some petty dispute of this nature or arising from this cause; one insisting that message is written "so and so, and *must* necessarily be so transmitted, while the other claims that there is "no sense in it," &c. In my humble opinion very few messages (cipher messages, of course, excepted) are offered for transmission which a little "common sense" (as "Buffalo" terms it) would not regulate so as to avoid all trouble of this kind. One more point of correction is in transmitting what are termed "obscure and difficult words." Too often is it the case that such words are "rushed" through with so much rapidity that the receiving operator must, of necessity, use his mental qualities for guessing, or cause more or less breaking; and, as we all desire to do as little of that as possible, such words are frequently the "bulled" ones, and when a message has been repeated a few times, the sender would, in many instances, be amused to see his message as it would then appear. I think many will agree with me, that no one thing could possibly conduce more to the interest of the Company than a general reform in these particulars.

"S."

SAN ANTONIO, TEXAS,
July 5th, 1872.

To the Editor of the Journal of the Telegraph:

Will you be kind enough to answer through the JOURNAL the following, which is a matter of controversy between offices:

"Can a message destined for an office on "other line" be sent checked paid *half* rate to our terminus, collecting tariff for other lines at full rates?"

N. J. PETRICH, Manager.

Answer.—No; unless the other line is a "half-rate office. Full rates for "this" and "other lines" should be charged.

WASHINGTON, MO., July 13, 1872.

To the Editor of the Journal of the Telegraph:

Will you please give me, through the columns of the JOURNAL, the law imposing a fine of one thousand dollars, or twelve months imprisonment in the penitentiary, for the divulging or making known the contents of a message?

WASHINGTON, MO., OFFICE.

Answer.—We are not familiar with the Statute laws of the State of Missouri. Ask your Superintendent.

To the Editor of the Journal of the Telegraph:

Is the Company legally bound to deliver prepaid telegrams at any point within the corporate limits of a city without additional charge?

ENQUIRER.

Answer.—No.

DEXTER, ME., OFFICE desires to know how many words there are in the following message:

"We have gone to M. H. Lake."

Answer.—From the face there are seven. It is impossible to say what M. H. Lake is, as it is written. It may mean Moosehead Lake, or it may be the name of a person. If the former, it being the name of a place, there would be but five words.

ANSWERS TO CORRESPONDENTS.

There are nine words in the following message:

"Our agent will be in Holly Springs Thursday or Friday."

The attention of the Manager of Jackson, Miss., office is called to the foregoing. Rule 9 is very explicit, and it covers this case exactly.

THE questions put by E. F. Knibloe of Hunt's station, are very indefinite.

The length of circuit that it is possible to work with "sounders" alone, and four common local jars, depends upon the size of the wire in the "sounder," the size of the line wire, and the strength of the battery. Under certain circumstances the *materiel* given above would be sufficient to work a circuit of two hundred miles.

M. KOHLFURST has devised an arrangement of a copper and zinc battery, somewhat similar to the Meidinger gravity battery, which he states will, if used for ringing electric bells, give a constant current for a year at the cost of 1½ lbs of crystals of sulphate of copper. A truncated hollow cone is thoroughly varnished inside, filled with crystals of sulphate of copper and placed mouth downwards in a glass jar deeper than itself. This cone has notches round the rim, and has a small hole in the center at the top. The positive pole is a thick cake of zinc suspended over the face of the cone; it is cast with a hole in the center through which passes a gutta percha covered wire, which is connected with the upper cone. The glass cylinder is filled with water, and it is evident that the rate of solution of the sulphate of copper depends upon the facility with which it is dissolved by the access of water through the notches in the cone, and as this takes place at a uniform rate the current given by the battery is uniform also. A dilute solution of sulphate of magnesia or common salt may be used instead of plain water, if it required to diminish the internal resistance of the battery.

ELECTRICITY seeks always an equilibrium in its distribution through matter. If there is an excess in one place, it always seeks to transfer itself to other places, where there is less, or a deficiency.

The production of electricity, from whatever source, is always twofold, or in two directions, one surface or part of our apparatus becoming always *positive*, while another becomes *negative;* thus suggesting the idea of a gain on one side, and loss on the other of a corresponding amount of electricity—in other words, of a *disturbance of equilibrium*. Thus the rubber and prime conductor of the electrical machine, the platina and zinc plates of the battery, and the antimony and bismuth of the thermo-electric pair, become respectively electro-positive and electro-negative, as the first condition and fact of electrical excitement.

THE electrical conducting power of a metal is diminished by heating it. A poor conductor is more easily heated by an electrical discharge than a good conductor. Thus a stroke of lightning that would fuse an iron rod would not injure a copper rod of the same dimensions. The conducting power of copper is 120, while that of iron is only 24.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory, and Province on the continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JOURNAL OF THE TELEGRAPH,

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, AUGUST 1, 1872.

SERVICE UPON ATLANTIC CABLE BUSINESS.

If there is one thing more surprising than the fact that it is possible to transmit intelligence beneath the waters of the broad Atlantic, it is the celerity with which that business is performed. In the average time upon each message transmitted between New York and London, the service is barely equalled by the best managed circuits wholly upon the land. For the seven days ending July 20, 1872, the actual time averaged upon messages exchanged between New York and London was 13 minutes and 59½ seconds. That is to say, that a telegram addressed to London, leaving New York at 9 A. M., New York time, reached its destination at a fraction less than 9:14 of same time. When the distance is considered, the fact that the message has to be rewritten four times—at Plaister Cove, Heart's Content, Valentia, and London, and that this is the average upon the whole business for the week, and not the time upon any one message—it speaks volumes for the business management and the skill of the operators engaged.

That the average time of this week was not exceptional we have ample proof upon the examination of the record.

An exact record is kept of every message by each of the Companies engaged in its transmission, the precise time of its reception at each office is taken, and from this a daily and a weekly average is made.

In this average, "press" and government despatches are included, which, from their much greater length than ordinary business messages, serves to place the average time somewhat greater than is really occupied in the transmission of business for the general public.

Messages between New York and London pass over the wires of four Companies—the Western Union, to Plaister Cove; the New York, Newfoundland and London, from Plaister Cove to Heart's Content; the Anglo-American, from Heart's Content to Valentia, and from Valentia to London, by the British lines.

On one of the seven days given above, the average time of transmission between New York and London was actually only six minutes and thirty-five seconds; and the shortest average time for messagess for the entire day over one of the four lines was one minute and four seconds.

It is difficult to see wherein this service can be improved, and yet efforts are being made to that end. Mr. H. H. Ward, Superintendent of the New York, Newfoundland and London Telegraph Company, and Mr. Stearns, the inventor of the improved duplex instrument, have left for Plaister Cove and Heart's Content to introduce the double transmitter upon the wires between those points, and the Western Union Company have under consideration the advisability of placing them upon the circuits between New York and Plaister Cove, and also to place Heart's Content in direct communication with New York, thus avoiding one re-writing. When these improvements take place, the average time of transmission between New York and London will be reduced to a minimum.

JUDGE PALMER has returned from his European trip, whither he had gone for "free air and out-of-door exercise," seeking by this means to recover his health, which had been somewhat impaired by a too close attention to his duties. Judging from the many countries visited in the course of his tour, the search for out-of-door exercise was very successful, and we are glad to be able to state that Mr. Palmer has been greatly benefitted thereby. During his absence of nearly seven months he visited all of the principal cities of Great Britain and the Continent, spending a month at Rome. Traversing the principal part of Spain, he crossed over from Gibraltar to Tangiers, in Africa, returning *via* Genoa. Altogether the trip was very enjoyable, leaving but one regret—that it could not last longer.

PRESENTATION.

MR. D. H. Fitch, at Moberly, Mo., was made happy last week by the presentation to him of a "Siemens' Universal Galvanometer," from some seventy-five of the operators of the St. Louis, Kansas City and Northern Railway; the occasion being the retirement of Mr. Fitch from the superintendency of the telegraph wires attached to that road. The usual speeches were made, and from the sentiments therein expressed, we should judge that Mr. Fitch was very popular with his subordinates. Altogether, a very happy, pleasant time was had. The galvanometer was imported at a cost, including a gold inscription plate, of over two hundred dollars.

THE contributions to the Reid Testimonial fund are reaching the Committee in gratifying amounts.

Mr. Reid sailed for Europe in the steamer Baltic July 6th, and expects to be at home again about the middle of September. So the time is short to accomplish all that is desirable. It is the wish of the Committee that whatever may be decided upon to present to Mr. Reid should be ready upon his arrival; and, in order that this should be the case, those who have subscribed, but not yet remitted, should at once do so.

We will shortly give acknowledgments of receipts.

ATTENTION is called to the advertisement, in another column, for a partner in the telegraph supply business.

WE have received a communication from Mr. S. J. M. Bear, of the Western Union Telegraph Office at Mitchell, Iowa, in which he claims priority of invention over Himmel, in the improved battery, a full discription of which we published in our issue of June 1, 1872.

The prominent feature of this battery, the inverted reservoir of sulphate of copper, he publicly exhibited to operators and others at St. Ansgar, Iowa, some years ago, and at the time of his invention he had a full description of the same sworn to before a Justice of the Peace. He has been experimenting ever since, and believes now he has the best form of battery known, and intends at once to apply for a patent.

J. M. WALKER, of Bluff City, Ill., wishes us to explain the theory of lightning rods; the protection they afford, and the style and manufacture considered best.

We regret to say that our education has been wretchedly neglected upon the subject of lightning rods; but in a general way we have an intuitive idea that they are presumed to attract atmospheric electricity and conduct it to the earth, at such times, among others, when the accumulation is so great as to endanger property at the time of its discharge.

From our own experience we have a great horror of lightning rod men; they are so persistent in their efforts to "protect" a man's property, and they come in such swarms, scenting out a new building as rapidly, and with as much certainty as a well matured mosquito does a nice fat baby, that we hesitate to express a preference for any particular style or manufacture, feeling certain that if we did so, the agents of the remaining nine hundred and ninety-nine styles would take an early opportunity to renew their calls upon us, a contingency which we are anxious to avoid. Let Mr. Walker address an advertisement to the effect of his letter to us, to the lightning rod men throughout the country, and, at the end of two weeks, if he then survives, we should be glad to publish his experience in the JOURNAL.

THE AUGUST MAGAZINES.

Scribner's Monthly comes to our table as fresh and as full of entertaining matter as ever. The leading artcles upon Yachts and Yachting, The Graphic Art, and the Island of Corfu are profusely illustrated. Much useful information is given under the heading of Nature and Science.

The Phrenological Journal for August maintains its high place among our leading monthlies. Its articles on Hon. Geo. I. Post; the Republican Nominees for President and Vice President, and Fisher Ames, whose portraits are given, are reliable sketches of eminent public men. There is also a good deal of interesting miscellaneous matter.

We have received the second number (August) of the *New Health Monthly*. Good as the first number was, this is far better. Among the contents we would note the first of a series of articles on Popular Physiology. Three Classes of American Girls; Electro-Therapeutics, by A. D. Rockwell, M. D. The Privileges and Penalties of Sex.

THE present address of Charles H. Hubbard is wanted. Will any one knowing his whereabouts please reply through the colums of the JOURNAL?

Also, the present address of A. J. McAnally and his brother F. McAnally. The latter is supposed to have gone West about four years since.

THE INDUSTRIAL EXHIBITIONS OF 1872.

The Forty-first Annual Exhibition of the American Institute in this city is announced to open, under more favorable auspices than ever before, on the 4th of September, 1872. The exhibition will be held in the large building at Sixty-third street and Third avenue, heretofore known as the Empire Rink, which has been purchased by the Institute, and fitted up expressly for its occupancy at a large expense. For many years these annual exhibitions have been, as it were, milestones of American progress, by which the public have been able to measure the active advance in every department of the arts. It is confidently believed by the managers that the coming exhibition will be by far the most successful one yet held. The Institute this year, and we think wisely, returns to its former custom of awarding medals and diplomas, for articles of superior merit.

The Third Cincinnati Industrial Exhibition will open on the same day as the American Institute, September 4th, and promises to be the finest and most extensive affair that has ever taken place in this country. New buildings have been erected by the association, which will afford an exhibiting space of about seven acres.

The managers have offered quite a list of premiums in the electrical and telegraphic line, among which are silver medals for the greatest improvement in telegraphy, and for the best telegraphic instrument for private use, and a bronze medal for the best burglar alarm telegraph. A silver medal is also offered for the best electric gas lighter. Any information required may be had by addressing the Secretary of the Cincinnati Industrial Exposition.

PICKETT'S MORSE MEMORIAL BUST.

Mr. Byron Pickett, the talented young sculptor, who was entrusted with the design and execution of the Memorial Statue of Prof. Morse, placed by the telegraphic fraternity of the country in Central Park last year, has just executed a small Memorial Bust of the late Professor, which has been warmly commended by the family and many personal friends who have examined it. This bust is sixteen inches high, and of what is called cabinet size, and is finished after the style of the celebrated Rogers Groups.

Mr. Pickett is an artist of superior ability, and we have no doubt but that he will find a large demand for this latest production of his chisel.

Attention is called to his advertisement in another column of this paper.

At the annual meeting of the stockholders of the Maine Telegraph Company, at Bangor, Me., June 26, the following directors were unanimously elected: Hiram O. Alden and W. H. Simpson, of Belfast; Albert W. Paine, J. A. Smith, Albert Hulton and William Gallup, Bangor; Bion Bradbury and W. P. Merrill, of Portland; and E. F. Littlefield, of Winterport. At a subsequent meeting of the directors, Hiram O. Alden was elected President, and W. P. Merrill, Secretary and Treasurer of the Board for the ensuing year.

Our thanks are due to Mr. and Mrs. I. W. Copeland for their kind remembrance, upon the occasion of their marriage, which, as announced in this issue, took place at Brandon, Vt., on Tuesday evening, July 9th. We hope that the happy and successful manner in which everything passed off may prove an augury of happiness and success in the future of the newly wedded couple.

THE MAYOR OF JEDDO AND MAYOR HALL.

The following telegraphic correspondence took place recently between the Mayor of Jeddo and Mayor Hall. So significant a desire as that expressed in the despatch of the Mayor of Jeddo finds a characteristic response in the despatch of the Mayor of the Empire City:

"San Francisco, July 25, 1872.

"To the Mayor of New York:

"The Mayor of Jeddo sends his respects to the Mayor of New York, the metropolis of America, the sails of whose commerce whiten the sea of the Orient, long isolated from western civilization. Jeddo now desires to learn and profit from the wisdom gained by the experience of other cities.

"K. Yuri, Mayor of Jeddo."

"New York, July 25, 1872.

"K. Yuri, Mayor of Jeddo, San Francisco, Cal.:

"A great citizen of New York, Commodore Perry, long ago made us first and best acquainted with Jeddo. Since his death, civilization, aided by her many servants, among whom is the Western Union Telegraph, has made Jeddo our valued neighbor and esteemed civic friend. The Atlantic metropolis joins with the Pacific one in congratulations on this pleasant meeting, either face to face, by the sunlight or the light of electricity. New York city wishes the Mayor of Jeddo a life long enough to see his city the perfect pride of a great empire.

"A. Oakey Hall, Mayor of New York."

Mr. M. H. Redding has been appointed Manager of the office in the New York Stock Exchange, in place of John Horn, Jr., resigned. Mr. Redding is an old and capable operator of many years experience among the brokers. The appointment is an excellent one.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR

Executive Office,
Western Union Telegraph Company.
145 Broadway, New York,
August 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since July 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff book as soon after the receipt of the Journal *as possible.*

NEW OFFICES.

140 Antwerp City, Pa.
* Big Oak Flat, Cal.
187 Blackshear, Ga.
* Bangor, Pa.
436 Conway, Iowa.
477 Choteau, Ind. Terr., re-opened.
329 Cobden, Ill., re-opened.
18 Cohasset Narrows, Mass.
113 Capon Springs, Va.
389 Cedar City, Mo.
59 Chester Heights, Pa.
261 Denver, Ind.
456 De Kalb, Mo.
387 Ely, Iowa.
483 Ennis, Texas.
271 Frankfort, Ind.
140 Fullerton, Clarion Co., Pa.
57 Five Mile Point, Otsego Lake, N. Y.
20 Fryeburg, Me.
* Gallatin, Mon.
165 Grahamville, S. C.
483 Hutchens, Texas.
375 Kenners, La.
280 Koutts, Ind.
Modesto, Cal., tariff same as San Francisco, Cal., heretofore an Other Line office.
59 Moselem, Pa.
18 Mattapoisett, Mass.
478 McAllister, Ind. Terr.
319 Mill Shoals, Ill.
* New Saybrook, Conn.
66 Nottingham Colliery, Pa., ck. Plymouth, Pa.
377 Port Allen, Iowa.
310 Ridgeway, Ill.
20 Sebago Lake, Me.
92 Shortsville, N. Y., re-opened.
Twilocks, Cal., tariff same as San Francisco, Cal.
169 Unionville, O.
201 Venice, O.
299 Waveland, Ind.
130 Worksburg, N. Y.
20 West Baldwin, Me.

SUMMER OFFICES RE-OPENED.

40 Catskill Mountain House, N. Y.
112 Cresson Springs, Pa.
* Ocean Grove, N. J.
39 Clarendon Springs, Vt.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.		*Leaves this Line.*
Bangor, Pa.	35	2	Portland, Pa.
Big Oak Flat, Cal.	75	35	Sonora, Cal., ck. San Francisco, Cal.
Gallatin, Mon.	100	7	Helena, Mon.
New Saybrook, Conn.	30	3	Hartford, Conn.

OFFICES CLOSED.

Godwinville, N. J.; Hawthorne, N. J.; and Monument, Mass.

GENERAL INFORMATION.

The following is a revised list of offices on the B., N. Y. and P. R.R. line, with "Tariff for Other Lines" from Buffalo, N. Y.:

Arcade, N. Y.	40	3	Buffalo, N. Y.
Elma, N. Y.	30	2	"
East Aurora, N. Y.	30	2	"
Eldred, N. Y.	55	4	"
Franklinvill, N. Y.	45	3	"
Holland, N. Y.	35	2	"
Ischua, N. Y.	50	3	"
Larabees, N. Y.	55	4	"
Machias, N. Y.	45	3	"
Port Allegheny, N. Y.	60	4	"
Protection, N. Y.	35	2	"
South Wales, N. Y.	35	2	"
Yorkshire Centre, N. Y.	45	3	"

Business for offices on the Alabama and Chattanooga line, named in last Journal, may be sent via. Meridian, Miss., if more direct than via. Chattanooga, Tenn., at the following "Rates for Other Lines:"

Attalla, Ala.	80	5	Meridian, Miss.
Carthage, Ala.	50	3	"
Collinsville, Ala.	90	6	"
Birmingham, Ala.	75	5	"
Eutaw, Ala.	50	3	"
Green Pond, Ala.	60	4	"
Livingston, Ala.	30	2	"
Morgansville, Ga.	100	7	"
Springville, Ala.	75	5	"
Trenton, Ga.	100	7	"
Toomsuba, Miss.	25	2	"
Valley Head, Ala.	90	6	"

Business for Lincoln, Mattawamkeag, Oldtown, Vanceboro and Danforth, Me., will hereafter be checked to Bangor, Me.

The "Tariff for Other Lines" from Lake City, Fla., to Fernandina, Fla., has been changed to 125 and 11.

Hereafter Edgecomb House, Groton, Conn., will be checked as an Other Line Office. "Tariff for Other Lines" 25 and 2 from New London, Conn.

CUBA CABLE BUSINESS.

The following offices were opened for public business on the Spanish Government lines in Cuba:

Tariff from Havana 40 cents gold for 10 words, and 40 cents for each additional 10 words or fraction thereof.

Mariel,
Cabanas,
La Mulata,
Bohia Honda,
San Diego de Nunez,

WILLIAM ORTON,
President.

TRANSFER SERVICE.

Executive Office,
New York, July 24, 1872.

To Transfer Agents:

All transfer messages must bear the time when received from the customer, as well as the time when transmitted by the operator.

On and after August 12th, *Wheatland, Pa.*, will be added to the list of Money Order Offices in C. O. Rowe's District.

G. H. MUMFORD, Vice-President.

NOTE ON RECURRENT VISION.

BY PROFESSOR C. A. YOUNG.

In the course of some experiments with a new double-plate Holtz machine, belonging to the college, I have come upon a very curious phenomenon, which I do not remember ever to have been noticed. The machine gives easily intense Leyden jar sparks from seven to nine inches in length, and of most dazzling brilliance. When in a darkened room, the eye is screened from the direct light of the spark, the illumination produced is sufficient to render everything in the apartment perfectly visible; and what is remarkable, every conspicuous object is seen twice at least, with an interval of a trifle less than one quarter of a second—the first time vividly, the second time faintly; often it is seen a third, and sometimes, but only with great difficulty, even a fourth time. The appearance is precisely as if the object had been suddenly illuminated by a light at first bright, but rapidly fading to extinction, and as if, while the illumination lasted, the observer were winking as fast as possible.

I see it best by setting up in front of the machine, at a distance of eight or ten feet, a white screen having upon it a black cross, with arms about three feet long and one foot wide, made of strips of cambric. That the phenomenon is really subjective, and not due to a succession of sparks is easily shown by swinging the screen from side to side. The black cross, at all the periods of visibility, occupies the same place, and is apparently stationary. The same is true of a stroboscropic disc in rapid revolution; it is seen several times by each spark, but each time in the same position. There is no apparent multiplication of a moving object of any sort.

The interval between the successive instants of visibility was measured roughly as follows:—A tuning fork, making 92½ vibrations per second, was adjusted, so as to record its motion upon the smoked surface of a revolving cylinder, and an electro-magnet was so arranged as to record any motion of its armature upon the trace of the fork; a key connected with this magnet was in the hands of the observer. An assistant turned the machine slowly, so as to a spark once in two or three seconds, while the observer manipulated the key.

In my own case the mean of a dozen experiments gave 0s.22 as the interval between the first and second seeing of the cross upon the screen; separate results varying from 0s.17 to 0s.30. Another observer found 0s.24 as a result of a similar series.

Whatever the true explanation may turn out to be, the phenomenon at least suggests the idea of a reflection of the nervous impulse at the nerve extremities—as if the intense impression upon the retina, after being the first time propagated to the brain, were there reflected, returned to the retina, and from the retina traveling again to the brain renewed the sensation. I have ventured to call the phenomenon "Recurrent Vision."

It may be seen, with some difficulty, by the help of an induction coil and Leyden jar; or even by simply charging a Leyden jar with an old-fashioned electrical machine, and discharging it in a darkened room. The spark must be, at least, an inch in length.

MAGNETIC sand is found in immense quantities on the sides of the volcano of Mount Ætna. The specific gravity of this sand is 2.813. Acids have little effect upon it. Analysis gives silica 52.71, magnetic oxide of iron 19.44, alumini 19.09, lime 6.61, magnesia 1.85.

LUMINOUS ELECTRICAL TUBES.

One of the most convenient methods of exhibiting the illuminating qualities of electricity is by means of the Geissler tubes, which now form part of the standard apparatus of colleges and other institutions of learning. The Geissler tube—so called after the inventor, Dr. Heinrich Geissler, of Bonn, Germany—consists of a glass pipe sealed at each end, and also provided at each end with a platinum wire which projects into the tube. The atmospheric air is exhausted from the tube, a small quantity of gas or vapor is introduced, and the tube is then sealed. When the two wires are placed in connection with a Rhumkorff coil, a stream of electrical light passes through the tube, taking various forms and colors, which vary with the kind and density of the enclosed gas. Hydrogen yields a white light; carbonic acid, green; nitrogen, yellow, etc. The most magnificent effects can thus be produced. A practical application of this discovery is a surgical lamp which consists of a small glass tube and bulb. The electric light is produced in the bulb, which may be introduced into cavities for medical examination.

Attention has lately been called to another kind of luminous tubes, also produced by Dr. Geissler, in which luminosity is produced without the use of the coil and electric battery.

Such tubes, which contain small quantities of certain gases, as nitrogen, carbonic acid, hydrogen, or ammonia, become luminous after being exposed to friction with any of the well known producers of electricity, as silk, wool, cotton, or even paper; the best, however, are catskin and prepared india rubber, which is now largely employed in the manufacture of combs, etc., and which is also used in the Holz electric machine. This mass is so very sensitive that it is sufficient to make the tube luminous after it has passed a couple of times through catskin, when it is not even touched, but held two or three inches distant. When a rarefied spiral glass tube was inserted in a larger plain tube, spontaneous discharges of light would continue within the former, even after the luminous state of the whole length had ceased for some minutes, and the color of the light is dependent on the quality of the traces of gas left within the spiral tube. The very curious researches of Dr. Geissler may possibly lead to a clue to the wonderful phenomenon of the aurora borealis.

BORN.

YEAKLE.—At Baltimore, July 14, 1872, to C. Clay Yeakle, of W. U. Telegraph Office, a daughter.

MARRIED.

BARNUM—LITTLEJOHN.—At Topeka, Kansas, July 24, 1872, E. E. Barnum, to Miss Christina D. Littlejohn, Manager of W. U.T elegraph Office, Topeka.

COPELAND—ROSS.—At Brandon, Vt., Tuesday, July 9, 1872, at the Congregational Church, Ithamar, W. Copeland, of Fishkill, N. Y., Supt. of the Dutchess County Telegraph Co., to Miss Mary J. Ross, of Brandon.

DAVY—ROBISON.—On June 20, 1872, at the residence of the bride's father, by Rev. Mr. Moore, J. V. Davy, Operator for the A. & T. Manufacturing Co., Mansfield, O., to Miss Mina Robison, of Shreve, O.

HUBBARD—EDWARDS.—At Champaign, Ill., July 10, 1872, in the First Congregational Church, by Rev. J. S. Frame, Mr. William Hubbard, Manager W. U. Telegraph Office, Monticello, Ill., to Miss Callie G. Edwards, of Champaign.

TAYLOR—HOLT.—At Delphi, Ind., June 27, 1872, by Rev. L. M. Stevens, George M. Taylor, Agent and Operator T. W. & W. Railway, at Clarksdale, Ill., to Miss Bell A., only daughter of Major A. W. Holt.

DIED.

LEUTZ.—Near Reno, Ind., July 15, 1872, Lucinda E., wife of S. R. Leutz, aged 22 years, 4 months and 13 days.

SMITH.—At Baltimore, July 22, 1872, Kirby Barnes, infant son of Robert H. and Annie B. Smith, aged two months and twenty days.

TELEGRAPHERS' INSURANCE ASSOCIATION.

The acknowledgement of receipt on any one assessment is to be understood as an acknowledgement of all previous assessments.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 18. NEW YORK, AUGUST 15, 1872. WHOLE NO. 115.

WHEATSTONE'S BRIDGE.

If the differential galvanometer were practically as perfect as it is theoretically, it would enable us to make nearly all electrical measurements with great accuracy; but the difficulty of adjusting the two halves of the coil so as to have, at the same time, equal resistances and equal inductive effects, prevents its use where minute accuracy is required, although it is well suited for making all the ordinary practical tests which are necessary in telegraphy. All the advantages, however, which could theoretically be anticipated from that instrument may be practically obtained by means of the Wheatstone Bridge, or Balance, as it is sometimes called.

The principle of the differential galvanometer consists in the arrangement of a coil composed of two wires of equal lengths and resistances, so that if currents of equal strength are sent through them in opposite directions the effect on the needle is nil. The principle of the Wheatstone Bridge is that of causing the compensating currents to pass in opposite directions through a coil composed of one wire by a peculiar arrangement of resistances. This arrangement obviates the difficulties mentioned in the construction of the differential galvanometer, because the movements of the needle are solely dependent upon the alteration in the relative values of the resistances, and in no way upon their inductive effect.

Figure 1 represents a board on which are placed four copper wires, Zb, Za, Ca, Cb, the extremities of which are fixed to brass binding screws. The binding screws Z, C, are connected respectively with the two poles of a battery, and those marked a, b, are connected with the ends of the wire of a galvanometer. By this arrangement a wire from each pole of the battery proceeds to each end of the galvanometer wire, and if the four wires be of equal length and thickness, and of the same material, perfect equilibrium is established, so that a battery however powerful will not produce the least deviation of the needle of the galvanometer from zero. The circuits Z b a C Z, and Z a b C Z, are in this case precisely equal; but as both currents tend to pass in opposite directions through the galvanometer, which is a common part of both circuits, no effect is produced on the needle. Currents are, however, established in Z b C Z and Z a C Z, which would exist were the galvanometer entirely removed. But if a resistance be interposed in either of the four wires, the equilibrium of the galvanometer will be disturbed. If the resistance be interposed in Zb or Ca, the current Z a b C Z, will acquire a preponderance. If it be inserted either in Za or Cb, the opposite current, Z b a C Z, will become the strongest. If the resistance interposed in the wire be infinite, or which is the same thing, if the wire, which we will suppose to be Cb, be removed, the strength of the current passing through the galvanometer will be that of a partial current Z b a, passing through one of the wires, plus the galvanometer wire; the path of the diverted portion of the current being Za. According to this disposition, the force of the original current $= \frac{E}{R+2r}$ +g, and that of the partial current acting on the galvanometer $\frac{Er}{R(3r+g)+2r^2+rg}$; R, being the resistance of the battery; r, that of a single wire, and g, that of the galvanometer.

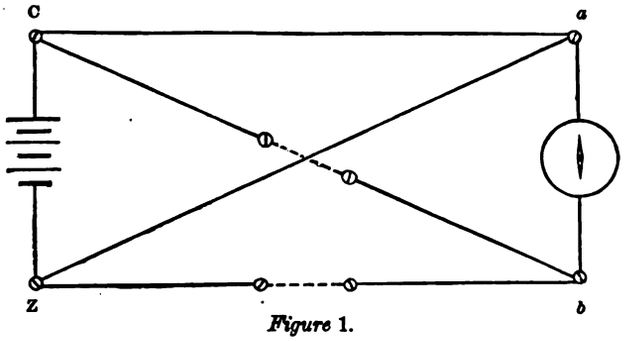

Figure 1.

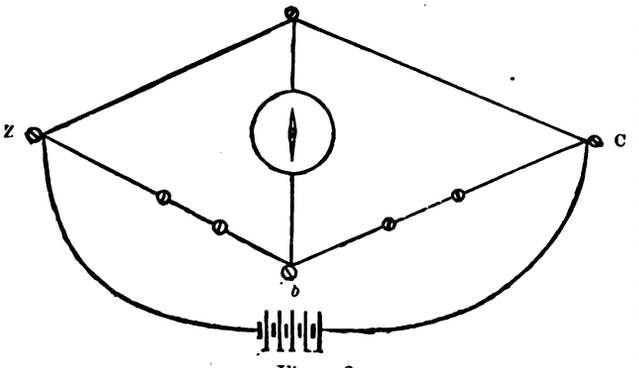

Figure 2.

The equilibrium having been disturbed by the introduction of a resistance in one of the wires, it may be restored by placing an equal resistance in either of the adjacent wires. For the purpose of interposing the measuring resistance or rheostat and the helix, wire or other resistance to be measured, the wires Zb and Cb are interrupted and provided with binding screws for the reception of the ends of the wires. The equilibrium when once established is not in any degree affected by fluctuations in the electromotive force of the battery.

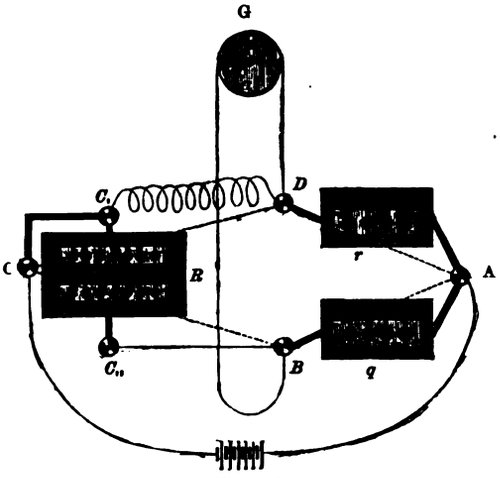

Figure 3.

Figure 2 represents another arrangement of the wires of the bridge in the form of a lozenge, whichis the one generally employed to describe the balance, although in practice the apparatus never bears this form. On comparing it with figure 1, it will be seen that the connections of the resistances and galvanometer in the two are identical, and that they are, in the second diagram, only put into a more convenient form. The latter diagram is more readily borne in mind, and affords great assistance both in comprehending the principle involved and in arranging the connections for a test. The same reference letters are employed, and the preceding observations apply to it equally.

The principle of the Wheatstone Bridge may perhaps be more readily understood, if we illustrate its operation by the variations in the tensions of the electric current upon the various parts of the balance, instead of the quantity of current passing through them, the latter being always proportional to the difference in tension between any two points on the conductor.

If we call the tension at the copper pole of the battery +, and that at the zinc pole —, the tensions in each branch of the bridge, providing the resistances are the same, will fall regularly and gradually from the end which is attached to the copper pole, and will rise regularly and gradually from the end which is attached to the zinc pole, until they both meet in the middle of the wire, where they will be at zero.

The circuit is always divided at some point in the bridge into two branches, and at this point the tensions are equal, while at some other point the two branches are united and the tensions are again equal, whatever may be the lengths of the two intervening circuits. If the resistances are the same in each branch, the tensions will be equal at any two points on the two branches at the same distance from either pole.

In diagram 2, the bridge is composed of four wires of equal length, size and resistances, with a galvanometer connected across at the junctions a and b, and the two poles of a battery connected respectively with C and Z. The current enters the bridge at C and divides into two equal portions, one half traversing the wire C b Z, and the other half traversing the wire C a Z. As the tensions at a and b are both at zero no current will pass between these two points and consequently the needle of the galvanometer is not affected.

Digitized by Google

Under the conditions above described the currents on a and C and b and C are both +, while those on b and Z and a and Z are both —. If a resistance be inserted in the wire b C, the zero point will change from b to a point nearer C, the tension at b will become — or less than zero, and a current will flow across the wire between a and b, through the galvanometer, proportional to the difference in tension at these points. If a resistance be now inserted between b and Z, equal to that between b and C, the zero point of the tensions will return again to b, and no current will pass between a and b.

When the needle stands at zero the following relations always exist between the four wires composing the bridge: If Za is equal to Zb, then Ca is equal to Cb; or if Za is equal to Ca, then Zb must be equal to Cb. When Za bears the same proportion to Zb that Ca does to Cb no current will pass between a and b, because the tensions in each branch of the circuit will change in the same proportion and will be equal at the junctions a and b.

Figure 3 represents an arrangement of the bridge suitable for the measurement of any resistance large or small.

A, B, C, D are the four terminal divisions of the bridge; r is a rheostat containing three resistance coils of 10, 100 and 1,000 ohms each; q is a rheostat exactly similar to the preceding, and these two rheostats are connected on one side with the + pole of the battery. On the other side, r is connected with the galvanometer G and the unknown resistance X, and q is connected with the rheostat R at $C_{,,}$ and thence with the — pole of the battery, to which the unknown resistance is also connected through $C_{,}$. The galvanometer G has a coil or multiplier containing about 22,000 turns of wire, and offers a resistance of 6,000 ohms.

The resistances in r and q being the same, in order to ascertain the resistance of X it is only necessary to calculate the resistance unplugged in the rheostat R to bring the needle of the galvanometer to zero, as the resistance inserted in R is exactly the same as the resistance of X.

It is always necessary to place some resistance in DA and BA when a considerable resistance is inserted between DC and BC, otherwise there would be no appreciable difference in the tensions at D and B, whatever the variations in the resistances of CB and CD might be. The greater the resistance to be measured, the greater should be the resistances inserted in DA and BA.

If the resistance of the wire, helix, cable or other substance to be measured which is inserted between C and D, is not greater or smaller than any of the resistances contained in the rheostat R which is inserted between CB, then by unplugging the proper resistance in R the needle will be brought to zero, and the resistance unplugged will be equal to the resistance of the material measured, for DA : BA :: DC : BC; and as DA is equal to BA, DC and BC must also be equal.

If the resistance to be measured is greater than that contained in the rheostat R, the resistance of q must be made less than that of r, and the resistance unplugged in R must be multiplied by the proportion which exists between r and q. If, on the contrary, the resistance to be measured is less than the smallest resistance in the rheostat R, q is made greater than r, and the resistance unplugged in R must be divided by the proportion which exists between r and q. For example, in measuring a resistance greater than that of the rheostat R, suppose q to have a resistance of 200 ohms, r 300 and R 10,000, then—

q : r :: R : X; or, 200 : 300 :: 10,000—15,000 ohms.

In measuring a resistance less than that of the rheostat R, suppose q to have a resistance of 25 ohms, r 5 and R 1, then—

q : r :: R : X; or 25 : 5 :: 1 : —.2 ohm.

The value of the unknown resistance X may also be determined by the following equation:

Let r represent the resistance inserted in DA, q the resistance in BA, R the resistance unplugged in BC in order to bring the needle to zero, and X the unknown resistance in DC, then $\frac{r}{X} = \frac{q}{R}$

It will be seen by examining diagram 3, that the three sides of the bridge DA, BA and BC, are really composed of resistance coils, the intervening wires or metallic rods having no appreciable resistance, and only serving as connectors between the coils. In practice it is quite common to unite r and q in one box, having two parallel sets of resistance of ten, one hundred and one thousand ohms. With the Wheatstone bridge, resistances can be measured ranging from .01 of an ohm to 1,000,000, with the same degree of exactness.

PROGRESS OF THE ELECTRIC TELEGRAPH.

The patent of Morse, who invented the first practical recording telegraph, was taken out in the year 1840; since then, numerous other modes of recording information at a distance by electricity have been invented, and there are now many systems in use, although the Morse telegraph in its various modifications is generally employed in all parts of the world for the general business of telegraphing.

It is curious that just ninety years after Dr. Franklin identified lightning with electricity, by means of his kite, Morse should have schooled electricity to send messages almost instantaneously over wire at great distances.

This all-pervading element manifests itself in countless ways—in the sparkling of animal hair; in the rustling of silk; in the aurora that illumines the North; in the meteor that startles the astonished observer; it flashes in the lightning bolt that rives the oak, without, while it gently penetrates into the lady's parlor and fills her form, as she glides over her warm, thick carpet, until the metal tube of the gas burner will receive enough from her fingers to ignite the gas. It will also convey to her the thoughts of distant minds with more than the assiduity of Puck, by means of the invention of Morse.

Morse was by no means the discoverer of the analogy between magnetism and electricity, but he was the first who made practicable all former discoveries and improvements in the production of a recording telegraph. The two leading properties of electricity that make telegraphs possible are: first, its constant desire to seek an equilibrium, always going where there is less; second, that different substances have very different conducting powers—over some it passes with the utmost freedom, while over others it will scarcely pass at all. On this depends the possibility of telegraphing, since by it the current of electricity may be arrested or conveyed at the will of the operator. Mr. William Sturgeon of London discovered in 1825 that when a bar of soft iron was placed within a coil of conducting wires it was rendered magnetic, and would so remain as long as the current of electricity passed through the wires. The telegraph consists in connecting two of these magnets by a wire of any number of miles in length, and directing through it a current from an electric battery. By throwing on and cutting off the current, the iron becomes alternately charged and at rest with great rapidity. To form the current, it is necessary that the wire should form a circuit, or that each end of the wire should communicate with the ground. The interruption is caused by stopping this communication. The first telegraph invented by Professor Morse consisted of an electro-magnet, formed by bending a small rod of iron in the form of a horse-shoe, upon which was wound a few yards of copper wire insulated with cotton thread. This magnet *h* was then placed upon the middle of a painter's stretching frame for canvas *x x*, the bottom of which was nailed to the edge of a common table. Across the lower part of the frame was constructed a narrow trough to hold three narrow cylinders of wood A B C. A wooden clock D was placed at one end of this trough. The cylinder C, next to the clock, had a small pulley-wheel fixed upon its prolonged axis, outside the trough; a similar pulley-wheel was fixed upon the prolonged axis of one of the slower wheels of the train of wheels outside the clock; these two pulley-wheels were connected by an endless cord or band. Upon the cylinder A, farthest from the clock, was wound a ribbon of paper, which, when the clock train was put in motion, was gradually unrolled, and passing over the middle cylinder B was rolled up upon the cylinder nearest the clock by means of the cord and pulleys.

An A shaped pendulum F was suspended by its apex *f* from the centre of the top of the frame, directly above the centre of the middle cylinder in the trough below. This lever was made of two thin rules of wood meeting at the top but opening downwards about one inch apart, and joined at the bottom by a transverse bar (which was close to the paper as it moved over the middle cylinder) and another about one inch above it. Through the centre of these two bars a small tube was fixed through which a pencil *g* loosely played. The pencil had a a small weight upon its top to keep the point in constant contact with the paper ribbon. Upon the lever directly opposite to the poles of the electro-magnet was fastened the armature of the magnet or a small bar of soft iron. The movement of the lever was guided by stops on the frame at the sides of the lever permitting it only a movement forward to and back from the magnet; the pencil at the bottom of the lever was thus allowed to advance when the magnet was charged and to retreat when discharged, about one-eighth of an inch. The lever advanced by the attraction of the magnet and was retracted by a weight or spring.

The voltaic battery I, or generator of electricity, was connected by one of its poles to one of the helices of the magnet, while the other pole was connected with a mercury cup; and a conjunctive wire connected a second mercury cup to the other helix of the magnet. The circuit was closed by dipping a forked wire into the two cups of mercury, when the magnet became charged, the armature was attracted, and the lever drawn toward the magnet. When the forked wire was removed the magnet was discharged and the spring brought back the lever to its normal position. When the clock-work was put in motion the ribbon of paper was drawn over the middle cylinder, and the pencil attached to the lever being in constant contact with the ribbon of paper traced a continuous line lengthwise with the ribbon.

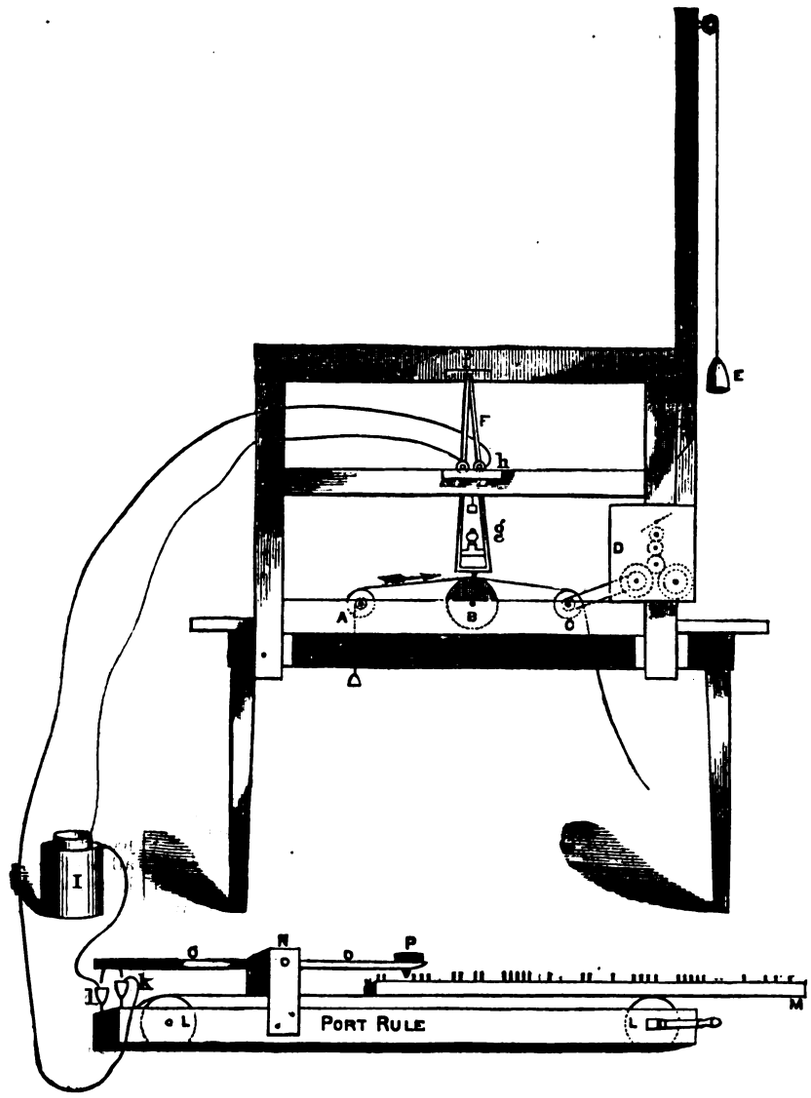
The pathway of the pencil point, when the lever was attracted towards and held by the magnet for a longer or shorter time, contains the three elements of points, spaces and lines, forming by their various combinations, the various conventional characters for numerals and letters.

At the time of the construction of this first telegraphic instrument, Morse had not conceived the idea of the present *key manipulator* dependent on the skill of the operator, but he presumed that the *accuracy* of the imprinting of signs could only be secured by mechanical mathematical arrangements and by automatic process.

Morse having ascertained that the machinery he had constructed, rude as it was, would move the ribbon of paper at a regular speed, and that the pen-

Digitized by Google

cil lever was obedient to the closing and opening of the circuit, the next thing to construct was the manipulator or regulator of the closing and opening of the circuit.



These were now to be put in use.

Morse prepared rules of composing sticks M, fig. 2, of about *three* feet in length each, formed by two strips of wood, so placed side by side as to leave a narrow channel large enough to contain the type in desired order and to allow the cogs of the type to project above the upper edge of the rules. Through and along the bottom of the rules projecting downwards were several needle points about one-fourth of an inch in length; their use will be perceived presently.

A long trough L L sufficiently wide to allow of easy passage of the rules through its length, was constructed with the following parts. Near each end of this trough were two small cylinders, of wood, L L. On the prolonged axle of one of them was a hand crank, and over the two cylinders an endless band of worsted tape about one and a half inches in width, which when the crank was turned passed from end to end of the trough. Midway and across the trough was erected a small frame or bridge N, within which a wooden lever O O was suspended parallel with the endless band, having its fulcrum at N at a point about two-thirds in length, but the longer part reaching from the fulcrum to the end of the trough, on each side of which under the end of the longer part of the lever was placed the *two cups of mercury* J K.

Upon the end of the lever and above the cups of mercury was fixed a forked wire so bent as to connect both cups when the end of the lever was depressed, and to disconnect them when it was raised. At the other or shorter end of the lever a weight P overbalanced the longer part, and on the under side beneath the weight was a beveled tooth projecting downwards. The rule or composing stick, having the type set up, was then placed upon the endless band; the needle points beneath the rule striking through the band and retaining the rule in its place. By turning the crank the rule was made to pass beneath the lever. The first cog of the type coming in contact with the tooth beneath, the weight of the lever raised that end and depressed the other, causing the forked wire to descend into the two cups of mercury, and *closing* the circuit. When the cog has passed the tooth, the weight caused the tooth to fall into the space between the first and second cog, and the fork at the other end of the lever to rise out of the cups of mercury *opening* the circuit. At each dip of the forks into the cups the circuit was closed, the magnet was charged, the armature on the pendulum lever was attracted and the pencil passed from the upper line A (figure 1) to the lower line B. When the fork was raised out of the cups the circuit was opened, the magnet was discharged and the pendulum lever with its pencil resumed its normal position by the action of the spring. A repetition of this process, as the rules with the type passed beneath the tooth on the lever, completed the action of the instrument.

Professor Morse subsequently modified the form of his telegraph, although the principle upon which its action depended remained substantially the same. In place of the wooden cylinders, operated by a wooden clock for carrying the paper band at a regular rate, he employed small brass rollers, moved by means of mechanism analagous to clock-work; and instead of the armature being attached to a wooden pendulum which vibrated over the paper, he attached it to one end of a brass lever sustained in a horizontal position by two pivots, the other end of the lever being armed with a steel

THE FIRST MORSE INSTRUMENT.

point. Under the soft iron armature at one end of the lever was placed an electro-magnet, while the steel point at the other end of the lever was beneath the roller which carried the band of paper. Now, when the circuit is closed—that is, completed—the armature of the electro-magnet is attracted through the magnetism created in the helix by the passage of the electric current, and this attraction causes the point of the pen to touch the paper and to trace upon it a line, the length of which depends upon the duration of time in which the circuit remains whole. If the circuit is opened, the current ceases to flow, the magnetism disappears instantly, and a spring attached to the lever draws it away from the paper, and the line ceases. By opening and closing the circuit rapidly, dots are produced upon the paper, the number of which depends upon the number of times that the circuit is broken and closed. If the circuit is closed for a longer time, a dash or short line is made upon the paper. We have thus the combinations of an alphabet of dots and lines. Thus A is a dot and a dash; B, a dash and three dots, &c. The alphabet is so arranged that those letters occurring most frequently are more easily transmitted; thus, E is one dot; T, one dash. An expert operator can transmit from thirty to forty words a minute by this instrument, on a land line of 200 or 300 miles in length.

The transmitting apparatus is very simple, being designed only for the opening and closing of the circuit in a manner more easy than by holding the ends of the wire in the hands, as is done where there is no apparatus, or by the port rule previously described. The two ends of wire are separated by two pieces of metal, one of which is a brass lever surmounted by an ivory button, and the other is a brass anvil tipped with platinum. The brass lever is mounted upon pivots, in front of the axis of which is soldered a nipple of platinum, which, by the depression of the lever, comes in contact with the platinum tipped anvil, and thus closes the circuit.

To the Morse system, at a latter period, was added the "sounder," a simple contrivance, by which signals are conveyed by sound. Up to 1850 the operator read the dispatch from slips of paper to the copyist, who wrote it down. It was soon found, however, that the dispatch could be read by the "click" of the instruments, and the operator now copies, himself, from sound.

Several modifications of the Morse telegraph have been made, the principal of which is to substitute ink marking for embossing. The Morse telegraph in its various modifications is now used almost exclusively throughout the world.

The number of inventions connected with the electric telegraph is almost endless, and would occupy several volumes for their description; but the only system at present in use for general telegraphic communication in the United States, besides the Morse, is the letter printing telegraph, invented by Mr. G. M. Phelps, and this instrument is only used in four out of the six thousand telegraphic stations in the United States.

Telegraphic stations must be united by one insulated wire, either carried overland or under the sea. The insulation of land lines is insured by attaching the wires to insulators, fixed on posts some twenty feet high. The posts are placed at distances of about sixty yards apart. Insulators are of all shapes and many materials. The insulator most generally used in the United States is made of glass, and is supported by a wooden pin. The leakage in a long line, notwithstanding the best insulation, is consid-

Digitized by Google

erable. The loss at each post is insignificant, but when hundreds or thousands are taken into account it becomes decided, so that, in extremely wet weather, in some cases merely a fraction of the total current that sets out reaches the earth at the distant station.

The wire most employed for land lines in the United States is No. 9 galvanized iron wire, although there is considerable of No. 8 and a few thousand miles of No. 7 and 6 in use.

But a little more than a quarter of a century has elapsed since the electric telegraph was introduced to the public as a practical means of communicating intelligence. The first line constructed in the United States was put in operation in the month of June, 1844, between Washington and Baltimore. Up to this time the electric telegraph had been regarded only as a curious theoretical science, without practical application. As far back as 1834 Messrs. Gauss and Weber constructed a line of telegraph over the houses and steeples of Gottingen, using galvanic electricity and the phenomenon of magnetic induction as a motor. The slow oscillations of magnetic bars, caused by the passage of electric currents, and observed through a telescope, furnished the signals for corresponding, but the operation was complicated, slow, and inefficient. In 1837 M. Steinheil established a line of telegraph between Munich and Bagenhausen, a distance of twelve miles; and in 1838 Professor Wheatstone constructed a line between London and Birmingham; but the apparatus employed by each was crude and unsatisfactory, and it was not until Professor Morse perfected his simple and reliable system that the electric telegraph became of practical utility.

During the first few years after the introduction of the electric telegraph, its progress was very slow. Capitalists were afraid to invest in an undertaking so novel and precarious. When one of the most distinguished financiers of New York was asked by the projectors to subscribe towards the construction of the first line from Baltimore to New York, he replied, that he would make them a present of a hundred dollars, but that he would not have his name associated as a stockholder in so wild and chimerical a scheme. After the line was completed, this incorrigible skeptic was amongst the first and best patrons of the Company.

As a natural consequence of the distrust of capitalists, and the great difficulty of raising funds for properly building the lines, they were constructed in a very unreliable manner, and breaks and interruptions was rather the nominal condition of the wires than the exception.

At the commencement of 1848, the length of telegraph wire in operation in this country was about 3,000 miles. At the present time there are over 160,000 miles in successful operation within the limits of the United States, having over 5,000 stations and employing upwards of 10,000 operators and clerks. The gross receipts of the various telegraph companies in this country amounts to upwards of $9,000,000 per annum, while the aggregate capital employed is more than $60,000,000.

The various uses to which the telegraph has been applied is almost innumerable. Among the most important of them may be mentioned its application to the running of trains on railroads; the giving of alarms of fires in our principal cities; its employment in scientific and astronomical observations, and the transmission of weather reports. Within the past few years a new field of usefulness has been opened and partially developed in the application of the telegraph to stock reporting and private line purposes, and in which it has already achieved a marked success, with the promise of becoming, in the future, a still more important branch of the business. The instruments used for this purpose print the despatches in plain Roman letters, without the aid of an operator, at the receiving station. Through the aid of this apparatus, stock and market quotations are received at the exchanges, banking houses, and other places of public resort in the chief commercial cities of the United States, at all hours of the day. This new enterprise, which was inaugurated in 1868, has become one of the most important features of the telegraphic business.

In Europe, the telegraphs, with the exception of the sub-marine lines, are nearly all owned and controlled by the Governments, and in England, they are connected with the Postal Service. In continental Europe the annual expenditures for the telegraphic service exceed the receipts by about two millions of dollars. In England the telegraphs were purchased by the Government in January, 1870. Since then the Government has expended about five millions of dollars in excess of the receipts, but, as a portion of this expenditure is for new construction, it is uncertain how great the annual discrepancy will be.

In December, 1870, a general system of telegraphic money orders or transfers was put into operation in the Pacific States. The public demand for the use of facilities for telegraphic exchange had long been apparent, and had induced the authorization of a limited amount of business, which was conducted with success and profit; but the need was felt of a system which could be adopted generally, without bringing in at the same time new and serious risks. This object has now been attained, and arrangements have been made for opening money order offices in all parts of the country.

The progress of the electric telegraph within the past six years has been very great in every quarter of the globe. Upon this continent the electric wire extends from the Gulf of St. Lawrence to the Gulf of Mexico, and from the Atlantic to the Pacific Ocean. Three cables span the Atlantic Ocean, connecting America with Europe, and another submerged in the Gulf Stream unites us with the Queen of the Antilles. Unbroken telegraphic communication exists between all places in America and all parts of Europe; with Tripoli and Algiers in Africa, Cairo in Egypt, Teheran in Persia, Jerusalem in Syria, Bagdad and Nineveh in Asiatic Turkey, Bombay, Calcutta, and other important cities in India, Hong Kong and Shanghai in China, Irkoutsk, the capital of Eastern Siberia, Kiakhta on the borders of China, Nagasaki in Japan.

A direct line of telegraph, under one control and management, has recently been established between London and India, with extensions to Singapore, Hong Kong, Java and Australia.

Europe possesses 450,000 miles of telegraphic wire and 13,000 stations; America 180,000 miles of wire and 6,000 stations; India 14,000 miles of wire and 200 stations; and Australia 10,000 miles of wire and 270 stations; and the extension throughout the world is now at the rate of 100,000 miles of wire per annum. There are, in addition, 30,000 miles of submarine telegraph wire now in successful operation, extending beneath the Atlantic and German oceans; the Baltic, North, Mediterranean, Red, Arabian, Japan and China seas; the Persian Gulf; the Bay of Biscay, the Strait of Gibraltar, and the Gulfs of Mexico and St. Lawrence.

More than twenty thousand cities and villages are now linked in one continuous chain of telegraphic stations. The mysterious wire, with its subtle and invisible influence, traverses all civilized lands, and passes beneath oceans, seas and rivers, bearing messages of business, friendship and love, and constantly, silently but powerfully contributing to the peace, happiness and prosperity of all mankind.

Professor Morse, who was already past middle age when he conceived the idea of the electric telegraph, on board of the packet-ship, Sully, on her ever memorable passage from Havre to New York, in 1832, and who was nearly three score years of age when his first line was built, lived to witness the consummation of his most ardent anticipations in the use of his invention throughout the world. The invention of Professor Morse, which, although yet in its infancy, has already conferred inestimable benefits upon the people of more than half the globe, without having occasioned a pang of sorrow to a single human being. If he is to be regarded as among the greatest of benefactors who makes two blades of grass to grow where but one grew before, with what affection should we cherish the memory of him through whom wars have been postponed and shortened, peace promoted and extended, time annihilated and distance abolished, and all the highest and noblest faculties of man multiplied, extended, and enlarged.

INVENTIONS AND INVENTORS.

There is a saying that "all great things have had small beginnings," and this is true, not only of electric telegraphs, but also of the great trade of electroplating, and of the magneto-electric machine which is now largely used instead of the voltaic battery. After Volta had made his small and, apparently, unimportant experiments on the electricity produced by metals and liquids, various persons tried the effect of that electricity upon metallic solutions. Bingnatelli, in 1805, found that two silver medals became gilded in a solution of gold, by passing electricity through them. Mr. Henry Bessemer, in 1834, coated various lead ornaments with copper by using a solution of copper in a similar manner. And, in 1836, Mr. De La Rive found that copies might be taken in copper of engraved copper plates by the electro-depositing process. Faraday discovered magneto-electricity in the year 1831, by rotating a disc of copper between the poles of a magnet, and he has stated that the first successful result he obtained was so small that he could hardly detect it. This simple experiment was the origin of the magneto-electric machine.

Persons inexperienced in scientific matters are apt to think that discoveries are generally made by accident. The reverse is, however, the case; nearly all our great modern discoveries were effected by men who were constantly making careful experiments upon the properties of matter and its forces, by subjecting them to new and definite conditions. Nearly all persons look upon such discoveries as fortunate ideas, which, when once found, are quickly developed, instead of which they are, in most cases, slowly developed results of most difficult mental labor.

Discoveries in science are occasionally made, not by original scientific investigators, but by practical men engaged in manufacturing or technical employments. The hydro-electric machine originated in this way: a man at Newcastle was attending to a steam boiler, and found that he received electric shocks when he touched the boiler. This circumstance was investigated by his employer, Mr. Armstrong, a scientific man, and led him to construct the hydro-electric machine. The accumulation of electricity in submarine telegraph cables was also first observed at the Gutta-Percha Company's works, London. It was noticed, on testing the cable by means of a voltaic battery (the cable being submerged in water) that discharges of electricity flowed from the cable after the battery was removed. This circumstance was investigated by Faraday, and led to improvements in submarine telegraphy. In these instances also the same general method was employed, viz., new experiments were made (though not intentionally,) by putting matter and its forces under new conditions, and new results were observed.

Nearly all the improvements which are made in machinery, manufactures, and trades are effected either by inventors who occupy their lives in making inventions and patenting them, or by practical men engaged in trades and manufactures.

FOREIGN TELEGRAPHIC ITEMS

TRANSANDINE TELEGRAPH.—The successful completion of the telegraphic line across the Andes, placing the Plate in immediate contact with Chili and the Pacific, is reported. The whole of President Errazuriz's address to the Chilian Chambers had been transmitted in less than fifteen hours, comprising over 4,000 words. The Argentine telegraph offices are so busy that this dispatch had to be forwarded by post from Villa Nueva to Buenos Ayres. This line is remarkable for the snow cable in the Andes. The engineer who carried out the work is Mr. Villanueva, under the direction of Messrs. Clark, of Valparaiso.

AN accident of unusual character happened a few days since to the short submarine cable which connects the Isle of White to the main land. The end of this cable is carried in shore along the bank of the river Yar, where it lies covered in the mud. A bull, which had taken it into his head to be fractious, after paying a visit to a chemist's shop, rushed down to the river bank, and there got into the mud just at the place where the cable lands. The animal, in its efforts to extricate itself, struck upon the cable and broke it. The cable, however, was speedily repaired, and is now in proper working order.

THE late thunder storms have done considerable damage to the Postal Telegraphs of the United Kingdom. Demagnetisation of needles, and in a large number of instances the fusing and complete destructions of the instrument coils, shows that the want of an efficient lightning protector is still much felt. Owing to the admirable arrangements of the service, however, little inconvenience will be found to arise from such accidents, to the public in general, although it calls for the most energetic endeavors of the Post-office Telegraph Staff to prevent such inconveniences from arising.

THE Australian Telegraph Company have announced their readiness to receive telegraphic messages for Australia and New Zealand, at the sender's own risk. The land line is not yet complete, but by means of an express service, news may be received in Adelaide five days after London dates. The work of construction in Australia has been divided into two parts, one from Port Darwin southward, the other from Port Augusta northward; of the former 400 miles have been constructed, of the latter 1,176 miles, leaving 250 miles incomplete. Great difficulties have been experienced from floods. If one walks a mile or two from the camp, he may find, on attempting to return, that he is almost cut off by creeks and water courses, which before had no existence. The rainy season would thus seem to threaten interruption to the line when constructed. Iron poles will further be wanted all through tropical Australia, on account of the ravages of the white ant. The company wishes to carry a submarine cable from Port Darwin to join the Queensland lines, in the Gulf of Carpentaria.

THE number of messages forwarded from postal telegraph stations in the United Kingdom, during the week ending July 13, shows an increase of 52,770 messages, as compared with last year.

THE total number of messages forwarded from postal telegraph stations in Great Britain, during the week ending July 20, 1872, was 304,853, an increase on the corresponding week of last year of 57,936.

CORRESPONDENCE.

FOLLOWING COPY.

SAVANNAH, Ga., Aug. 9, 1872.

To the Editor of the Journal of the Telegraph:

It is not my intention to assume an arbitrary position in reference to sense *versus* nonsense, nor do I think my reply to "Buffalo" is open to the inference that the exercise of common sense in matters appertaining to the personal affairs of any individual, should in any manner be prohibited or abridged; but I assume that a company possesses the right to establish regulations and limitations as to the operation of their interests entrusted to any agent employed by it, and that so long as a restriction exists upon the proceedure of that agent, in any direction, it should not be deviated from in any particular. The expediency and judiciousness of the regulation can be discussed with perfect propriety, but a violation of it is neither legitimate nor wise under any circumstances, and if persisted in by the corporate authority which enacted it, the result would be speedy confusion and peril to the interests of that company. The experience of all corporate institutions has demonstrated that where any regulation allows a discrimination in its application, it will invariably result in suppressing the legitimate intent of the enactment, and render it practically inoperative to the accomplishment of its original purpose. The reason is, that any license would naturally result in an indefinite and infinite infringement. While some individuals, possessing judgment sufficient to interpret the proper definition of the license, and a comprehension of the extent required, would use a discriminative privilege with wisdom, justice and moderation, others, by ignorance, recklessness, selfishness, or a disregard of the responsibilities involved, might assume it as a guarantee of their right to exercise their opinions and judgment, whenever and wherever they desired so to do. It thus appears to me, that while the extension of a privilege of personal judgment to those qualified to exercise it, might be of benefit to the company, inasmuch as it is virtually impossible to frame any enactment that will be broad and comprehensive enough to cover all possible cases and contingencies. Yet, the difficulty of ascertaining and measuring the competency of each individual agent, the danger of partial regulations, and the possibility of making unfortunate selections in conferring this privilege, and thereby jeopardizing the interests involved, renders the expediency of a change in the present regulations exceedingly questionable. This requirement of the company from their employés, which it regards as essential to the proper maintainance of their system of business, cannot interfere with the intellectual acquirements or the natural abilities of any one concerned. It is simply that the *principal* restricts his *agent* to a certain line of proceedure which that agent must adhere to, regardless of his individual preferences as to the questions of sense or policy involved.

I have had considerable experience with every description of business entrusted to Telegraph Companies, have seen many peculiar forms of expression, many illegible, obscure and apparently senseless messages, and have also seen many which appeared to resemble an impression taken from the inscription on some ancient monument; but after having satisfied myself that I understood it as the clerk received it from the party sending it, I never considered that I had any right to change it on the supposition that I could improve its orthography or general grammatical construction, because the receiving clerk is presumed to have made all necessary inquiries. If an opinion exists in the mind of the operator that it would be beneficial to have alterations made in a telegram, he can with perfect propriety and sense refer it back to the receiving clerk for his attention, but he should under no circumstances alter or amend any message placed on file for transmission, because he knows nothing of the intentions of the writer—has no basis for judgment beyond his self-created suppositions; and lastly, because the rules of the company employing him, and held responsible for the correct transmission of the message, expressly prohibits it. SAVANNAH.

ATHENS, PA., July 30, 1872.

To the Editor of the Journal of the Telegraph:

How many words are there in the following message?

"Will come up in the morning and bring you statements, *etc.*" "Etc," being the only question upon which there is any doubt; please answer through the JOURNAL. S.

Answer.—Etc, et cetera; two words.

WHITE HAVEN, PA., August 6, 1872.

To the Editor of the Journal of the Telegraph:

DEAR SIR:—Will you please inform me, through the medium of the JOURNAL, the number of words in the following message:

"Your sister-in-law died at half-past five, this P. M. Answer." RUSTIC.

Answer:—Ten words,

LEXINGTON, Ill., July 27, 1872.

To the Editor of the Journal of the Telegraph:

Suppose a message to be left at an office on the morning of 27th July, dated 26th, sender having paid for it and gone, must the message be transmitted as taken, or should an operator correct the date.

Answer:—Operator should, in sending, state that it was filed on the 27th.

ROME, Ga., July 31, 1872.

To the Editor of the Journal of the Telegraph:

Please answer the following question:

A man comes in the office to send a message; said man can't write and requests operator to write it; owing to bad articulation, errors occur in writing message. Who is responsible for such errors? Would it not be best to refuse such request by supplying man with No. 2 blank and let outsider write it. Or are we justified in writing it?

OCCASIONAL.

Answer:—Write the message, but let the customer sign it, or make his mark.

To the Editor of the Journal of the Telegraph:

Suppose I receive a message August 1st, dated San Francisco, July 31st, must I include that message in August Report. Having sent in Report for July!

REGISTER.

Answer:—Yes, with special explanation.

To the Editor of the Journal of the Telegraph:

Can the sender of a "red" message, have it repeated back, upon the payment of one-half of the amount of tolls charged for sending the message.

INQUIRER.

Answer:—Yes.

To the Editor of the Journal of the Telegraph:

By answering the following, you will oblige:

In a message, how many words are "A. M." (meaning forenoon), counted. Please answer through the next number of the JOURNAL. BUSY.

Answer:—One.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory and Province on the Continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JOURNAL OF THE TELEGRAPH,

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, AUGUST 15, 1872.

NIGHT MESSAGES AT HALF RATES.

It is well known that the bulk of telegraphic correspondence is presented for transmission between the hours of 9. a. m. and 3 p. m., and that for the greater proportion of the twenty-four hours the wires are but partially occupied. In order to utilize the wires during those portions of the day and night, when they were comparatively idle, the Company, in the Spring of 1867 introduced the new feature in telegraphy of offering to transmit messages at night, to be delivered the following morning, at a reduced rate. For this class of business a sliding scale was adopted, 20 words being sent at night at the cost of 10 words by day; 60 words at night at the cost of 20 by day; 120 words at night at the cost of 30 by day, and each additional 100 words at night at the usual cost of a 10 word mesage.

The number of night offices to which messages could be sent at the reduced rates was limited to forty of the principal cities, but such messages could be received for transmission to the above mentioned places at any office, and sent therefrom after 6 o'clock p. m., to the nearest night office on the route to its destination.

The moderate degree of success which attended this limited experiment in the transmission of messages at night at reduced rates, induced the Company to inaugurate a new feature in this service, whereby its benefits might be still further extended through the introduction of a uniform half rate system, and accordingly it was announced that on and after the first day of January, 1870, messages would be received at and for all stations on the Western Union lines in the United States east of the Mississippi river, including St. Louis, for transmission during the night and delivery the next day, at one-half the usual tariff rates, the limits being subsequently extended so as to include all stations on the Montreal, International Ocean and other connecting lines, as well as all Western Union stations in the United States east of Omaha.

Among the chief causes which led to the inauguration of the half rate system, was the constant demands which were made on all sides for additional wires to meet the increasing traffic of the Company, while, at the same time, those already in use were comparatively idle for the greater portion of the night and the earlier hours of the day. It was apparent that the half rate plan, if it should meet with success, must necessarily result in one of two things —the creation and development of an entirely new traffic, or the taking away of a portion of the full rate business which was transacted during the day. If it created a new business which the full day rates failed to reach, it would be performing a good service; while on the other hand, if it secured a portion of the full rate messages, it would relieve the wires during the busy hours of the day, and make room for the transaction of new full rate despatches, and thus prevent, or postpone, the necessity of putting up additional wires for an increased service.

The half rate system proved to be a popular measure from the beginning, and early developed a considerable business. During the past two years it has steadily increased in volume each month, averaging in 1870 about eight per cent., and now amounts to about eleven per cent. of the whole traffic.

Although the half rate business is already very large, we believe it is not so large as it would be, but for the fact that it is not made sufficiently prominent. In many offices there seems to be little effort made to encourage the half rate business, from the mistaken idea that it tends to diminish the receipts. So far from this being true, we believe that a discontinuance or diminution of the half rate system would decrease the receipts of most of our offices. But be this so or not, the policy of the Company is to increase the transmission of messages at night at half rates as largely as possible, until the wires shall be as fully occupied at night as they are during the day. For this purpose every Manager is expected to do all he can to increase this traffic. Placards announcing the fact that messages can be sent at night at half rates should be conspicuously posted in every office, and advertisements conveying similar information should be inclosed in every telegram delivered, so that every man and woman may know that telegrams can be sent over the Western Union wires at night and delivered the next morning at half the usual rates. The Officers of the Western Union Company desire to cheapen the rates of telegraphing as much as is possible, consistent with a due regard to the rights of the stockholders, with a view of popularising and increasing the business, and they believe that the extension of the half rate business is one of the most practicable and efficient modes of accomplishing this result. We hope all employees of the Company will cordially co-operate in forwarding the liberal views of the Company in this matter, and that we shall soon see a material increase in the number of night messages traversing our wires.

Mr. C. H. Foster has been appointed Superintendent of the telegraph lines belonging to the Indianapolis, Bloomington and Western Railway, *vice* T. G. Golden, resigned.

THE TELEGRAPH AND THE PRESIDENTIAL ELECTION.

The free use of the telegraph for the reporting of important speeches to distant localities increases the general interest in our national politics, and tends to bring about a greater uniformity of opinions. For instance, Secretary Boutwell delivers a speech in North Carolina, and the next morning it is reported in full in our morning papers. There is the same promptness in reporting Senator Fenton's speech at Albany. Both are upon the financial issues of the campaign. Both go before the country at about the same time, and present both sides of the case—not to a limited constituency, but to millions of readers. So this morning a long and elaborate speech, made by Carl Schurz last evening, at St. Louis, is reported as fully in our city journals as though it had been delivered at Cooper Institute. To-night Senator Conklin speaks here, and his speech will be read to-morrow by those who heard Senator Schurz last night.

Thus, no matter where or what, or how large the local audience may be, all of the first class efforts of the campaign are really addressed to the readers of newspapers all over the country. The contest loses much of its narrowness by this very fact. A speaker who feels that he is addressing a nation is not so apt to descend below the higher levels of controversy. The arena is too large, and mere local issues and petty personalities sink into their proper insignificance.

The vast constituencies that are now addressed through the aid of the telegraph ought to produce an elevating and enlarging effect on the speakers themselves, while the people, who read first class speeches instead of listning to bitter and commonplace harangues, must be immeasurably benefited by the reading of the able speeches on both sides that are of sufficient importance to be reported by telegraph. They find the question of the day handled with breadth and vigor, and become interested in discussion of the principles of our Government. Only what is strongest and best in the great speeches sinks deeply into the popular consciousness. The froth and scum of debate are transitory and soon forgotten.—*The New York Evening Mail.*

We are in receipt daily of letters on the business of the parties writing, and, as a rule, there is neglect in not inclosing a stamp for return postage. If this occured only once in a while it would not be worthy of remark, but where our average outlay equals twenty-five cents per day for postage upon matters relating to business not our own, it becomes a tax.

We expect, hereafter, in the class of communications here referred to, to find a stamp for return. The accommodation on our part is sufficiently great, when we give our correspondents our time and labor.

Speaking of the North Carolina election in connection with the Western Union office at Raleigh, N. C., the *New York Herald* of 8th inst. says:

"The interest manifested in this election is attested by the marvellous feats of telegraphing performed at this office. From Thursday night to Wednesday morning, intermitting only Sunday, not only were the lines busy with the press, but thousands of messages to individuals were transmitted, keeping Manager Stark and his two assistants at their instruments from noon until daylight the next morning every day since Thursday. The amount of telegraphing for the *Herald* and other New York papers far exceeded all the business ever done at this point for the same length of time, to say nothing of the private business, which has been twice as much more.

THE WESTERN ELECTRIC MANUFACTURING COMPANY.

Attention is called to the card of Messrs. Gray & Barton, of Chicago, Ill, in our advertising columns, announcing the transfer of their works and business to the Western Electric Manufacturing Company, and to the circular of the new Company, of which Gen. Anson Stager is President. This Company have, in addition to the works of Gray & Barton, purchased the Western Union Telegraph shops at Ottawa, Ill., and have largely increased their manufacturing facilities in addition, and are prepared to carry on the manufacture and sale of telegraph instruments and supplies on an extensive scale. The new Company is probably the largest of its kind in the United States, possessing unsurpassed facilities for accomplishing the vast amount of work heretofore carried on by its predecessors, and which, doubtless, will now be greatly augmented.

THE following statement shows the route of the West India and South American Telegraphs connecting with the International Ocean Lines at Havana:

From	*To*	*Miles.*	
Havana	Batabano, Cuba	42	land
Batabano	St. Jago de Cuba	560	cable

Total number of miles		3,295	

Arrangements are being made to carry on the line to Surinam and Cayenne.

Sir Chas. T. Bright is now engaged in laying cable between Jamaica and Aspinwall.

WE are in receipt of a communication from S. R. Jones, Lancaster, Pa. From what we gather in reading it, (and it is not very clear), we should advise Mr. Jones to patent his invention and then sell it. If it is of any real value he will have no difficulty in disposing of it.

BORN.

HOTZ.—At Lancaster, Pa., to Jacob Hotz, a daughter.

MARRIED.

DAVIS—BOSH.—At Sharon, Pa., June 11, 1872, by Rev. Henry Camp, J. C. Davis, Manager W. U. Telegraph office, Girard, Ohio, to Miss Jennie Bosh, of Girard.

DIED.

DORMAN.—At Stafford Springs, Conn., July 13, 1872, Carrie E. Dorman, aged 19 years and 2 months.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
August 15, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since August 1, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff books as soon after the receipt of the JOURNAL *as possible:*

NEW OFFICES.

437 Atchison Junction, Mo.	233 Ludlow Grove, O.
25 Brookfield, Mass.	* Lowell, Neb.
21 Braintree, Mass.	* Lake Mohonk, N. Y.
18 Bristol Ferry, R. I.	41 Menlo Park, N. J.
305 Canoe Station, Ala.	21 Marshfield, Mass.
226 Conyers, Ga.	* Mooresville, N. Y.
18 East Stoughton, Mass.	18 North Abington, Mass.
327 Ellsworth, Ill.	36 North Hoosick, N. Y.
29 East Hampton, L. I. N. Y., re-opened.	10 Orono, Me., check Bangor, Me.
29 East Lyme, Conn.	18 Plympton, Mass.
242 Franklin, Warren Co., O.	130 Pioneer., Pa., re-opened.
41 Godwinville, N. J., re-opened.	21 Scituate, Mass.
102 Howard, Centre Co., Pa.	331 Saltillo, Miss., re-opened.
18 Holbrook, Mass.	427 Spickards, Mo.
18 Hanson, Mass.	481 Trinity, Texas.
25 Indian Point, R. I.	347 Tremont, Ill.
67 Kirkwood, Del., re-op'n'd	272 Velonia, Ind., re-opened.
	103 Weaverton, Md., re-open'd.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.		*Leaves this Line.*
Lake Mohonk, N. Y.	25	2	New Paltz, N. Y.
Lowell, Neb.	165	11	Plattsmouth, Neb.
Mooresville, N. Y.	45	3	Rondout, N. Y.

OFFICES CLOSED.

Beattie, Ks.; Edgerton, Mo.; Chehaw, Ala.; Essex, N. Y.; Goodmans, Fla.; Greensboro, Ga.; Laurel, Del.; Marianna, Ark.; Maywood, Ill.; Mannington, W. Va.; Norwood, N. J., Wetumpka, Ala., and Westover, Md.

GENERAL INFORMATION.

The following is a revised list of offices on the Chesapeake and Ohio R. R. Line, with "tariff for other Lines" from Greenbrier, White Sulphur Springs, and Huntington, W. Va.

Bowyer's Ferry, W. Va.	60	4 Greenbrier, W.S. Spg's, W.Va.
	65	4 Huntington, "
Big Bend Tunnell "	40	3 Greenbrier, W.S.Sp'gs, W.Va.
	65	4 Huntington, "
Barboursville, "	65	4 Greenbriar, W.S.Spg's, W.Va.
	35	2 Huntington, "
Coalburg, "	65	4 Greenbrier, W.S.Spg's, W.Va.
	50	3 Huntington, "
Charleston, Kanawha Co. W.Va.	65	4 Greenbrier, W.S.Spg's, W.Va.
	50	3 Huntington, "
Hurricane, "	65	4 Greenbrier, W.S.Spg's, W.Va.
	40	3 Huntington, "
Kanawha Falls "	65	4 Greenbrier, W.S.Spg's, W.Va.
	60	4 Huntington, "
Miller's Ferry "	60	4 Greenbrier, W.S. Spgs, W.Va.
	60	4 Huntington, "
New Richmond, "	50	3 Greenbrier, W.S.Sp'gs, W.Va.
	65	4 Huntington, "
Stretcher's Neck, Tunnell. W.Va.	50	3 Greenbrier, W.S.Sp'gs. W.Va.
	65	4 Huntington, "
St. Albans, "	65	4 Greenbrier, W.S.Sp'gs, W.Va.
	40	3 Huntington, "

Business for offices on B., N. Y. and P. R. R. line named in last JOURNAL may be sent via Olean, N. Y., if more direct than via Buffalo, N. Y., "tariff for Other Lines," as follows:

Arcade, N. Y.	25	2	Olean, N. Y.
Elma, N. Y	40	3	do
East Aurora, N. Y.	40	3	do
Eldred, Pa.	25	2	do
Franklinville, N. Y.	25	2	do
Holland, N. Y.	35	2	do
Ischua, N. Y.	20	2	do
Larabees, Pa.	25	2	do
Machias, N. Y	25	2	do
Port Alleghany, Pa.	25	2	do
Protection, N. Y.	30	2	do
South Wales, N. Y.	35	2	do
Yorkshire Centre, N. Y.	25	2	do

Eidred, Larabees, and Port Alleghany, Pa., were incorrectly given in last JOURNAL, as in New York.

The name of the office heretofore known as Hillsburg, N. S., has been changed to Bear River, N. S., and 120, Pine Grove Warren county, Pa., has been changed to Russellburg, Pa.

The tariff to East Hampton, L. I., N. Y., from offices in squares 1 to 40, inclusive, and 45 and 46, will be 15 cents more than tariff to square 41.

Hereafter business for Falconers, N. Y., will be checked to Jamestown, N. Y., and for Sugar Notch, Pa., to Wilkesbarre, Pa.

The P. O. address of Moselem, Pa., is Nora, Berks County, Pa., and of East Lyme, Conn., is Niantic, Conn.

Newport, Ky., is a W. Union office, tariff same as Cincinnati, and should be checked direct. See JOURNAL of May 1, 1872.

WILLIAM ORTON,
President.

TELEGRAPHERS' INSURANCE ASSOCIATION.

MAGNETISM.

The French Academy of Sciences has received a paper from M. J. Jamin, in which he shows that magetism may be condensed, just like electricity. Having, for some special purposes, had a large horse-shoe magnet made, consisting of ten laminæ of perfectly homogeneous steel, each weighing ten kilogrammes, he suspended it to a hook attached to a strong beam, and, having wound copper wire around each of the legs, which were turned downwards, he put the latter into communication with a battery of fifty of Bunsen's elements, by which means the horse-shoe might be magnetized either positively or negatively, at pleasure. The variations were indicated by a small horizontal needle, situated in the plane of the poles. There was, further, a series of iron plates, which could be separately applied to each of the laminæ. Before attaching any of the latter, the electric current was driven through the apparatus for a few minutes, and then interrupted, whereby the magnet acquired its first degree of saturation, marked by a certain deviation of the needle. One of the iron plates (usually called "contacts") was then put on, and it supported a weight of 140 kilogrammes. A second trial was now made; and the current having passed through again for a few seconds, it was found that the horse-shoe would support 300 kilogrammes, instead of 140. The number of contacts being now increased to five, which together, in the natural state, supported 120 kilogrammes, it was found, after the passage of the current, that they could support the enormous weight of 680 kilogrammes, which they did for the space of a full week. No sooner, however, were the contacts taken off than the horse-shoe returned to its usual permanent strength of 140 kilogrammes. This leads to show that magnetism may be condensed like electricity for a short period.

DISPERSION OF ELECTRICITY IN GASES.

The gradual loss of electricity by charged conductors, supported by solid insulators, and surrounded by air, is due, according to Coulomb, to two causes: first, the imperfect insolating power of the supports, and second, the action of the atmosphere, inasmuch as the small particles that are in contact with the conductor are electrified and driven away, giving place to fresh unelectrified particles, which are influenced in their turn similarly.

Coulomb found that charges which did not exceed a certain limit of electric density were perfectly insulated by the better insulators; this limit varied according to the insulating power of the substance used. For lower densities, the loss of electricity took place only by the atmosphere; and he found that the time in which the charge was reduced to an aliquot part of its amount has a constant value.

If Q denote the quantity of electricity in the conductor at time t, and Q_0 the quantity at the commencement, then

$$Q = Q_0 e^{-\frac{1}{2p}t}$$

where e is the base of a logarithmic system, and $2p$ is the time in which a charge Q is reduced to $\frac{1}{e}$ Q. According to Riess—$\frac{1}{p}$ is smaller in proportion to the quantity of electricity in the enclosed air of the balance employed.

Dellman experimented with moist air, and Matteucci with various dry gases—carbonic acid, air, and hydrogen. According to the latter, the loss is the same in all gases.

Professor Warburg prosecutes the subject in a recent paper in Poggendorff's "Annalen." The experiments he describes were conducted according to Coulomb's method, in which, the diminution in repellent force between two metallic discs kept at constant distance in a tension balance indicated the loss of electricity.

The results arrived at are briefly these:—

1. The loss of electricity from a charged body by its insulating support is greater the further this insulator is from a certain state of electrification into which it is brought; but the loss gradually approaches a small constant value, which it takes many hours to reach.

If the insulator be regarded as a bad conductor, then, where the difference in potential is great, there is a considerable escape of electricity in the insulator; where the difference is small (the insulator having reached the electrical state referred to), the escape is small. Experiments on the dispersion of electricity in gases ought therefore only to be made when the insulating supports have come to this fixed state.

For shellac cylinders, 1 m.m. diameter and 20 m.m. length, to which are attached metallic discs, 17 m.m. diameter, the loss by the supports, if these are little or not at all electrified, is large in comparison with the loss by air, while it is small in the opposite case. Thus the loss from both sources may be separated and measured.

2. The dispersion of electricity in gases proceeds according to Coulomb's law already stated.

3. The dispersion is found to be nearly the same in dry carbonic acid and atmospheric air; in hydrogen, only about half as great as in these gases.

4. The co-efficient of dispersion is considerably reduced on a reduction of the pressure from 760 m.m. to 380 m.m.; and at 70 m.m. pressure (in air) it is only one-third as great as 760 m.m.

5. Moist air does not give a much greater dispersion than dry air.

6. The dispersion of positive electricity, and that of negative, takes place at same rate.

DEEP SEA SOUNDINGS BY ELECTRICITY.

A correspondent of the *Scientific American* writes as follows:

The want of a means by which the depth of water at sea for soundings may be obtained expeditiously, certainly, and without stopping the vessel's way, howsoever fast she may be going through the water, has been long felt by seamen. Doubtless many disasters, resulting in the loss of vessels, lives and cargoes, might have been averted had the captain taken the precaution of frequently sounding, but when running "on time," the delay of getting a fair "up and down" cast is often too great, and captains prefer to, and often do risk getting into shoal water rather than lose the time required to sound. Of all the contrivances now in use, so far as known, to obviate the difficulty, probably Massey's patent is the best, but even that is defective and liable to error.

Fortunately, by the aid of electricity, a ship running along a coast at night, or approaching the land in thick weather, may, without "luffing to" or "slowing down," keep constantly sounding and obtaining the depth of water with rapidity and precision. Indeed, should the vessel suddenly strike shoal water, the fact is made known the instant the lead touches the bottom, without waiting to haul it in.

It is known by experiment that a lead of a determined shape and weight, with its line attached, will sink in sea water at a certain rate per second. On getting a cast of the lead, then, it is only necessary to ascertain the time the lead takes to reach the bottom in order to know the depth of water.

This is accomplished as follows: The lead line contains a heart composed of two insulated copper wires. The inboard end is connected with a small battery, and, by means of an armature, with a clock. The other end is bent to the lead.

The lead contains two insulated copper wires passing through its length, the upper ends connecting with those of the line. The lower ends, tipped with platinum, are slightly exposed beyond the surface of a false bottom or upper section of the lead. The lower section of the lead acts as a plunger, with a play of about one-eighth of an inch.

On striking the bottom the plunger is thrown up, so that a "button" on its upper surface comes in contact with the two platinum points, thus closing the circuit. This is known on deck by the instantaneous stoppage of the second hand of a clock, and the sounding of a gong attached to the clock, the purpose of the gong being to call attention.

The clock is an ordinary time-piece, with the addition of a second hand pivoting at the centre, and long enough to reach the perimeter of the face, where are marked the fathoms corresponding to the minutes.

Let it be supposed, for example, that a ship running along the coast at night should, at a certain hour, be, by the chart, in forty fathoms of water. The captain orders a cast of the lead and about forty fathoms of line to be used, the lead weighing say fifty pounds. At the instant of heaving the lead the second hand is set in motion and commences its regular beats; but instead of passing on to seventeen seconds, which is seen, on the face of the clock, to correspond to forty fathoms, the gong suddenly strikes its warning, and the hand is arrested at four seconds, which is seen to correspond to ten fathoms; the captain is thus warned of his dangerous proximity to shoal water, and at once hauls off.

A reel fitted in some convenient place aft should be used for reeling in the line and for keeping it in good order. The battery used is simple and inexpensive, and will keep in good working order for eight or nine months, and the clock, gong, and battery may all be contained in a case not larger than an ordinary ship's binnacle.

Connected with the same, battery wires may be led throughout a ship for signal purposes, such as for communicating with the man at the wheel, with the engine room, &c., &c., though if the wires be greatly multiplied, the strength of the battery must be increased in proportion.

POWERFUL GALVANIC BATTERY.

Mr. H. Highton communicates the following to the *Mechanics' Magazine*:

It may interest your readers to know that the cheap and simple battery made up as follows is nearly 50 per cent. higher in its potential than a Grove battery, and more than 150 per cent. higher than a Daniell:—

For positive, zinc in a solution of caustic potash or soda; for negative, carbon in a porous cell packed with precipitated sulphur, peroxide of manganese and granulated carbon, filled up with dilute sulphuric acid. The internal resistance is rather great, but if common salt be used with the zinc the internal resistance is much less, but the potential only a little more than 10 per cent. higher than a Grove.

This is a very cheap and convenient form of battery, and, I think, on the whole, the very best that can be used for ordinary purposes.

NEY'S BATTERY.

This cheap and convenient battery is constructed as follows: It consists, in the first place, of a glass vessel, filled with a solution of sal-ammoniac; then of an amalgamated zinc plate, which dips into the vessel. Further, of a porous cylinder of clay, standing in the same vessel, and filled with carbonate of copper, in which a plate of copper is suspended. For field and telegraph purposes, it is well to fill the glass vessel with fine sand, saturated with sal-ammoniac solution, instead of the pure solution itself. It is only necessary to add the crystal sal-ammoniac from time to time, in order to keep this battery in constant activity. The carbonate of copper is itself insoluble in the sal-ammoniac solution; but under the influence of the galvanic current, the sal-ammoniac is separated into the hydro-chloric acid and ammonia, the first of which attaches itself to the zinc, and the latter to the salt of copper, and dissolves it. During the reduction, a secondary current is produced, which is equivalent in strength to that of a Daniel's battery.

PERIODICITY OF STORMS.—M. Charles Sainte-Claire Deville read not long since a memoir before the *Academie des Sciences*, on quadruple symmetries and their application to the study of electric and atmospheric phenomena. He brought forward evidence to show that storms, auroras, etc., almost always occur after periodic intervals of ninety, thirty, and ten days. Also that there is a periodicity attached to the thirteenth, fourteenth, and fifteenth days of the month, as shown by the reports of the Meteorological Office. During the last two years, two or more of the days of from the 11th to the 15th of every month have been marked by winds, rain, squalls, thunder storms and auroras. Furthermore, a symmetry of phenomena can be detected at the dates 4th, 13th, and 24th of each month, of which M. Deville cited numerous examples.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 19. NEW YORK, SEPTEMBER 2, 1872. WHOLE NO. 116.

SIEMENS UNIVERSAL GALVANOMETER

The Siemens Universal Galvanometer, as its name would imply, is intended to meet all the requirements of a measurer of electric forces and resistances. The instrument consists of a comparatively sensitive galvanometer, which can be turned in a horizontal plane, combined with a Wheatstone Bridge and three resistance coils of 10, 100 and 1000 units respectively.

For measuring the strength of a current, the instrument is used as a sine galvanometer. For making measurement of electromotive forces, Professor E. du Bois-Reymond's modification of Poggendorff's compensation method is employed. For measuring conducting resistances, the instrument is used as a Wheatstone's Bridge.

The unit of measurement employed with this instrument is the Siemens mercury unit, representing the resistance of a prism of pure mercury one metre long and one square millimetre section, at 0° C. The ohm is equal to the resistance of a prism of pure mercury 1.0486 metres long and one square millimetre section, at 0° C. One Siemens unit—.9530 ohms.

Figure 1 shows a plan, and figure 2 an elevation, of the instrument.

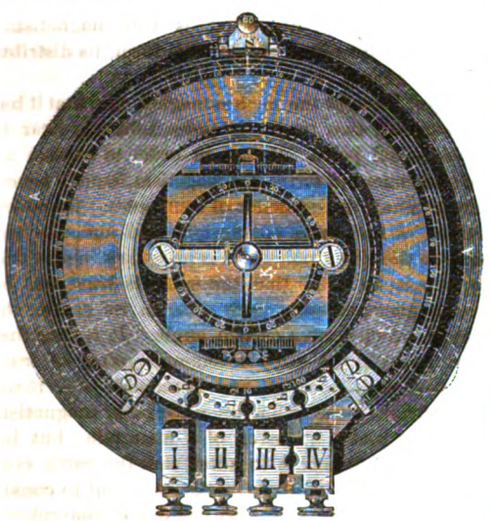

Figure 1.

A is a circular plate of polished wood, supported upon three levelling screws, *b b b*.

In the centre of A a metal boss is inserted, in which turns the vertical pin a, which carries the instrument. This pin, being well fitted to the boss, supports the instrument firmly, but at the same time allows it to be turned freely round its vertical axis without losing its horizontal position when once this has been obtained.

To the pin *a*, is attached a circular disc of polished wood C, about one inch thick, and having a groove turned in its edge for the reception of the insulated wires composing the artificial resistances. The disc C has a projection *c*, which carries the four insulated terminals marked I., II., III., IV., as shown on fig. 1.

The terminals marked III. and IV., can be connected together by means of a plug.

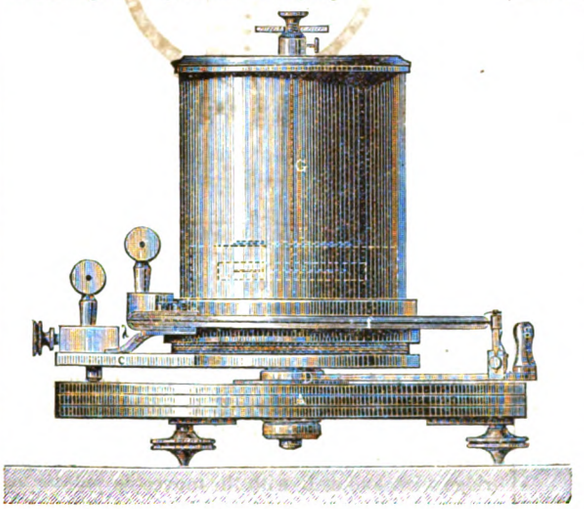

Figure 2.

Over C rests a somewhat larger disc of slate, the greater part of the circumference of which is turned to a true circular curve, but the part of this disc which is immediately above the projection c, on the lower disc, is cut out so as to leave a gap.

This slate disc carries in its centre the galvanometer G, and in front of it, along the gap, four insulated terminals, h_1 h_2 h_3 h_4, which may be connected with each other by means of plugs, and to the ends of which the wires of the artificial resistances are connected, as shown in fig. 3.

The galvanometer offers nothing extraordinary in its arrangement. It has an astatic needle system suspended from a cocoon fibre and a flat bobbin frame, wound with fine wire. The needle swings above a cardboard dial divided into degrees; as, however, when using this instrument the deflection of the needle is never read off, but the needle instead always brought to zero, two ivory limiting pins are placed at about 20 degrees on each side of zero.

The cocoon fibre is fastened to the knob K. One end of the convolutions of the galvanometer wire is connected to terminal h_1, on the slate disc, and the other end is terminal IV., as shown in the accompanying diagrams.

A slight groove is turned in the edge of the slate disc, and in this a tightly stretched wire made of platinum or German silver is inserted in such a manner that about half its diameter protrudes beyond the slate. The ends of the wire are soldered to two brass plates *l* and l_1, which are placed at the angles formed by the sides of the gap in the slate disc. The plate *l* is permanently connected by a thick copper wire or metal strip to terminal h_1, and the other plate l_1 is connected in a similar manner to terminal III.

Slate is adopted for the material of which to make the disc *f*, because it is found by experience to be the material which is least sensitive to variations in the weather or temperature. The slate disc is graduated on its upper edge through an arc of 300 degrees, zero being in the centre, and the graduations figured up to 150 on each side at the terminals *l* and l_1 of the bridge wire.

On the arm D, which turns on the pin *a*, and somewhat behind the handle *g*, there is a small upright brass arm *d* turning between two screw points *r*, and carrying in a gap at its upper end a small platinum jockey pulley *e*, turning on a vertical axis. This pulley forms the movable contact point along the bridge wire, against which it is kept firmly pressed by means of a spring acting on the arm *d*. The arm D, which is insulated from the other parts of the apparatus, is permanently connected with the terminal I. On the top of *d*, a pointer Z or a vernier is fixed, which laps over the upper edge of the slate disc and points to the graduations.

Figure 3 represents the connections to be made when using the instrument as a Wheatstone bridge for measuring conducting resistances.

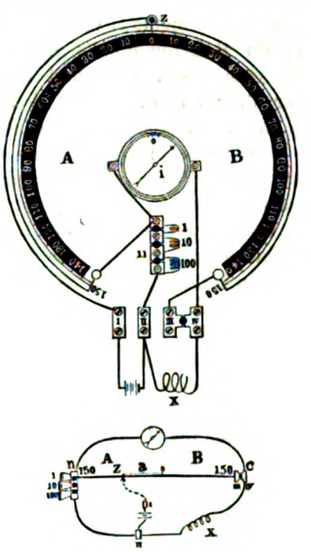

Figure 3.

The needle *i* is to be brought to the zero point of the scale by turning the galvanometer G round its vertical axis. The pointer or vernier Z is to be brought by means of the handle *g*, to the zero point of the large scale on the slate disc. A plug is to be inserted between the terminals marked III. and IV.. Two of the holes marked 10, 100 and 1000 are to be plugged and one left open, according to the extent of the resistance to be measured. 10 or 100 must be left open if the resistance is small, and 1000 if it is large. The two ends of the wire, helix or other unknown resistance to be measured are to be connected to terminals II, and IV. Connect the + pole of a battery with terminal I. and the — pole with II.

The lower diagram of fig. 3 represents the modifi-

Digitized by Google

cation of the Wheatstone bridge which is employed in this instrument. The proportion between the unknown resistance X and the artificial resistance n, when the deflection is read off on the side of the slate disc marked A, is as follows:

$$X : n = 150+a : 150-a \text{ or, } X = \frac{150+a}{150-a} \times n.$$

When read off on the B side of the disc

$$X = \frac{150-a}{150+a} \times n.$$

When the connections have been made with the instrument as shown in figure 3, the needle i may be found to deflect to the right hand or B side of the instrument, and the pointer or vernier Z may then be pushed by means of the handle g also to the B side of the instrument until the needle is brought to zero; or if by moving the vernier to the B side, the deflection of the needle is increased, the pointer Z should be pushed to the other or A side of the instrument beyond the zero point of the large scale and until the needle is brought to the zero point of the small scale. If when this is done the pointer Z stands at 50° on the A side of the large scale and at the same time at n the plug is out which puts the 100 units of artificial resistance into circuit, the following proportion will be obtained:

$$150-50 : 150+50 = n : X$$

$$X = \frac{200 \times 100}{100} = 200 \text{ units.}$$

If the needle is brought to the zero point of the small scale, while the pointer Z stands at 50° on the B side of the large scale, and the 100 unit resistance plug is removed, the following porportion will be obtained:

$$150+50 : 150-50 = n : X,$$

$$X = \frac{100 \times 100}{200} = 50. \text{ units.}$$

For making measurements of electromotive forces, Professor E. du Bois-Reymond's modification of Poggendorff's compensation method is employed.

The upper diagram of figure 4 shows the connections to be made with the instrument. The needle i is to be brought to the zero point of the small scale by turning the galvanometer G round its vertical axis. The pointer, or vernier, Z is to be brought by means of the handle g to the zero point of the large scale on the slate disc. The hole between III. and IV. to be left unplugged. Plugs to be inserted in 10, 100 and 1000. The two poles of the battery E_0 (which must be greater than E_1 and E_2) are to be connected with the terminals II. and III. The poles of the battery which is to be compared to E_0 are to be connected to terminals I. and IV. in such a manner that the similar poles of the two batteries are joined to terminals I. and III. and to II. and IV. respectively.

The galvanometer needle will now be deflected, and can be brought back to zero by turning the pointer Z either to the right or the left. Should for instance the pointer have to be brought to 30° on the A side, we have the following equation:

$$E_1 = E_0 \frac{150-30}{300+u} \text{------(1),}$$

where u is the resistance of the battery E_0.

The battery E_2 is now to be inserted in the place of E_1, and the galvanometer needle, when it deflects again, brought back to zero by moving the pointer Z. If for instance the pointer has to be pushed to 40° on the B side to obtain an equilibrium, we have:

$$E_2 = E_0 \frac{150+40}{300+u} \text{------(2.)}$$

By eliminating u from equations 1 and 2 we have:

$$E_1 : E_2 = (150-30) : (150+40) = 12 : 19 \text{------(3.)}$$

The two electromotive forces are in the same proportion as the two observed distances of the pointer Z from 150° on the A side of the instrument.

The lower diagram of figure 4 shows the arrangements of the circuits for comparing the electromotive forces by this method. The more powerful battery E_0 is connected at II. with one end of the resistance coils n, and at III. with

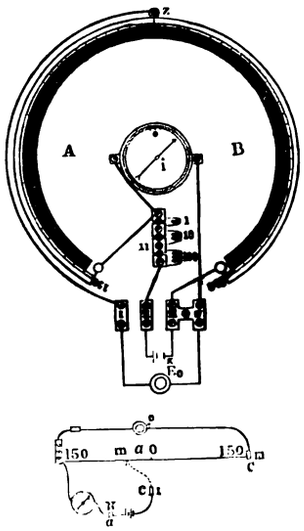

Figure 4.

the other end of the resistance coil, through the bridge wire. The battery E is connected at IV with one of the termini of the galvanometer coil, whose other end is connected with one end of the bridge wire, and at I. with the moveable pointer, or vernier, Z. The current from E_0 enters the resistance coils at II. and passes through them to the bridge wire, where two paths are open for its return—one *via* the bridge wire direct and the other through the galvanometer, the battery E and the vernier Z to

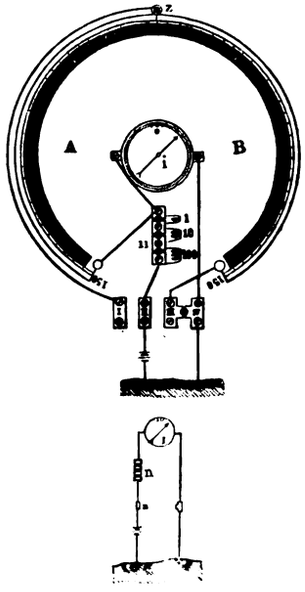

Figure 5.

the bridge wire. The current from E enters the bridge wire near the resistance coils n and traverses the former until it reaches the pointer Z, whence it returns. By moving the pointer until the tension is the same at IV. as it is at the junction of the bridge wire and the resistance coils n, no current will flow through the galvanometer.

For measuring the strength of a current, or the quantity which is passing over a conductor, the instrument is used as a sine galvanometer. Figure 5 shows the connection of the wires for this purpose.

The needle i is to be brought to the zero point of the small card-board scale by turning the galvanometer G round its vertical axis. The pointer, or vernier, Z is to be brought, by means of the handle g, to the zero point of the large scale on the slate disc. The hole between III. and IV. to be left unplugged. Plugs to be inserted in 10, 100 and 1000. Connect one pole of a battery to terminal II. and put the other pole to earth. Connect the line to terminal IV. The galvanometer is then to be turned in the same direction as the needle is deflected until the needle coincides with the zero point. Whilst this is being done the large scale on the slate disc will move under the pointer Z, which must be left stationery; the sine of the angle pointed by Z will then give the value proportionate to the strength of the current.

TERRESTRIAL MAGNETISM.

The magnetic force of our globe is manifested at its surface by three classes of phenomena; namely, the *declination* of the magnatized needle, its *inclination*, and the *intensity* with which the force acts. The declination is the angle that is formed with the direction of the meridian of the place by the direction of the magnetized needle placed upon a vertical pivot. The inclination is the angle that is formed with the horizon in the magnetic meridian by the direction of a magnetized needle sustained by its centre of gravity, around which it is able to turn freely in a vertical plane. These three elements, declination, inclin tion, and intensity, vary not only from one place to another, but in the same place, with time. They also manifest irregular and accidental variations, designated under the name of *disturbances*, and the existence of which is connected with some natural phenomenon, such, in particular, as that of the aurora borealis.

It is well established that the forces which act upon the magnetized needle emanate directly from the terrestrial globe. But what is this magnetism? Where does it reside? What is its form, its distribution, its origin?

Gilbert thought the earth a magnet, and that it has consequently two magnetic poles, tolerably near to its terrestrial poles. Halley, in order to explain all the phenomena of terrestrial magetism, found it necessary to admit the existence of four poles. Hansteen arrived at the same conclusion, and assigned the place to these four poles. It is necessary, under this hypothesis, to admit that the earth is traversed by two magnets, crossing each other in its centre, the axes of which form a certain angle. It is true that there exists in the earth a magnetic oxide of iron, endowed with polarity, and Humboldt has made some curious observations upon the polar magnetism of certain rocks, and even of a mountain; but besides our being unable to admit that the earth contains a quantity of these rocks sufficient to constitute terrestrial magnetism, we could not comprehend to what would be due the regular distribution which their magnetic polarity would assume. Gauss considers that the whole mass of the globe is magnetic, and that there exist a great number of magnetic centres.

Mr. Barlow, after having demonstrated that neither the presence of a single magnet, nor the arrangement of several magnets in the interior of the globe, could produce the phenomena of terrestrial magnetism, considers that, on the contrary, we may very well account for them by assuming, as Ampère did, *electric currents*, circulating around the terrestrial globe in a direction very nearly from east to west. He has endeavored to confirm this hypothesis by distributing upon the surface of a wooden globe a series of electric currents, arranged so as to produce upon a magnetic needle, not subject to terrestrial influence, and

Digitized by Google

placed in divers positions, the same kind of action that the earth imparts to it in analogous positions.

De la Rive considers that the forces which produce terrestrial magnetism have their origin in the solidified portion, that is, in the solid crust of the terrestrial globe, which does not prevent the points of application of their resultants being in the interior of the globe, more or less near to its centre; and hence the idea of electric currents circulating in this solid envelopo, and forming a solenoid more or less complicated, appears to him most natural. But whence arise these currents, and what is the cause by which their direction is determined? In order to explain atmospheric electricity, a production of electricity is assumed, resulting from chemical actions which take place in the interior of the terrestrial globe; but we cannot comprehend how this development of electricity should give rise to currents circulating from east to west. This direction must evidently be connected with the movement of rotation of the earth, which takes place from west to east; and consequently it is only in the existence of *induced currents*, arising from a magnetic action exterior to the earth, but susceptible of being exercised upon it, that the confirmation may be found of the hypothesis of Ampère, adopted by Mr. Barlow.

Indeed, the inductive currents are connected, more or less, according to their direction, with the direction of the movement of the induced body; and we know that on causing a body to rotate rapidly on its axis, under the influence of a magnetic pole, we are able to produce in it continuous induced currents. But where would the inducing body be, when the terrestrial sphere is in question? Evidently, it could only be found in the moon or in the sun. The moon plainly exercises an influence over the movements of the magnetized needle; but this influence is very feeble, and nothing enables us to discover traces of magnetism or of dynamic electricity in the moon, the mass of which, besides, is too small in respect to the earth for us to suppose that it can act upon it. It would be much more likely that the earth should act upon the moon.

It is only in the sun that we can find a body exterior to the earth capable of exercising upon it an inductive action. The sun appears to possess powerful electro-dynamic proprieties, for it is very probable that its light is due to energetic electric currents, which surround it, from the fact that the electric light, which plays between two carbon points that communicate with the two poles of a battery, bears a stronger resemblance to it than any other.

That the magnetic influence of the sun is not a gratuitous hypothesis, we find a proof in the agreement that exists between the magnetic movements upon the surface of the earth and the various positions of the sun in respect to the places of observation. Endeavors have been made to explain this agreement by an indirect action of the sun. M. Aimé attributed the diurnal variations of the magnetic elements to thermo-electric currents, all emanating from the most heated point,—a point which, changing its place with the sun, must make the turn of the globe in twenty-four hours; so that, in every place on the earth, except upon the parallel in which is the centre of the action, the direction and the force of the currents change throughout the day. But this hypothesis has against it, independently of a general objection, the small probability of the existence of thermo-electric currents upon the surface of the earth, either on account of the imperfect conductibility of this surface, or on account of the enormous proportion of water that it presents, which is not susceptible of thermo-electricity.

Faraday attributes the magnetic variations to the magnetic properties of the oxygen of the atmosphere,—properties which follow, in their degrees of force, the variations of temperature, in such a manner that heating reduces and cooling exalts them.

Father Secchi concludes from all the phases which the variation of declination undergoes, that *the sun acts upon the magnetized needle as if it were itself a large magnet, placed at a great distance from the earth, and having its poles of the same name as those of the earth turned to the same side of the heavens.* But in order to recognize the accuracy of these laws, regard must be had to the inverse action which the needle undergoes on the part of the sun in the twenty-four hours, by the effect of the rotation of the earth, the front of the needle that faces the sun being different at noon and at midnight, and the earth being interposed at the second epoch.

There are, however, other causes which affect the magnetized needle. M. Arago observed, on February 19, 1822, an extraordinary agitation in the needle of diurnal variations, and there was at the same moment a strong earthquake in Auvergne, at Lyons, and in Switzerland. Mr. Gray likewise observed in Valdivia, on the western coast of South America, a very remarkable disturbance in the magnetized needle at the period of a terrible earthquake which took place in those latitudes in February, 1836. But among all natural phenomena, there is one whose connection with terrestrial magnetism is so well established that we have, in the movement which the magnetized needle suffers, a proof of its presence, namely, the aurora borealis.

DURATION OF ELECTRIC SPARK.

Two methods have hitherto been employed in the determination of this. One is that of Wheatstone, in which a small mirror is made to rotate at a high velocity round an axis in its own plane, and the image of a spark is observed in it. In this way the discharges from batteries have been made to give images elongated in the direction of rotation; showing a sensible duration in the spark. By measuring the elongation and the velocity of rotation, the duration may be ascertained.

The other method is that of Arago, in which a disc with white sectors on a dark ground is made to rotate about an axis perpendicular to its plane, and the enlargement of the sectors in the light of the spark affords a means of determining the duration of the latter.

MM. Lucas and Cazin recently described to the Paris Academy a method which gives somewhat more precise results, and on which a Committee of the Academy have reported favorably.

They employ a moveable disc, (made of plates of mica), the rim of which is situated between the observer's eye and the spark. On the rim are traced very fine lines, transparent and equidistant, and which are obtained by photographic reproduction. This disc is placed before a second opaque disc of the same diameter, which is fixed, and has on its rim seven fine lines, comprising six divisions, with a width which is equal to five divisions of the moveable disc, so that this second disc forms a vernier, by which the one-sixth of a division of the first disc may be estimated.

The spark appears in the focus of the lens of a collimator, which gives the rays (passing to the vernier) a direction parallel to the axis of rotation of the moveable disc. On the opposite side of the discs a small telescope is placed for observation of the luminous effects.

If the spark has an inappreciable duration, the observer may either see a bright line, or he may not. In the former case, the spark appears at the moment of coincidence of a line on the moveable disc with one on the fixed disc; in the latter case, the spark appears between two coincidences. There is, however a certain probability of coincidence of lines and spark, depending on the breadth of the lines on the discs, and also the number of those on the vernier. This has been determined experimentally for the apparatus now considered, equal to 0.70; *i. e.*, that if an instantaneous spark be produced at any instant, then, out of 100 instances it will give a bright light 70 times, while 30 times it will give none.

Suppose, now, the duration of a spark is a little greater than that of the passage of a line on the moveable disc before two lines on the vernier, then, if the commencement of the spark happens at the instant of the first coincidence, the bright line from this coincidence will (owing to persistence of impression on the retina) continue visible at the time of the second coincidence, and two lines will thus be seen at once.

If, with the same duration, the spark commences between two coincidences, it will have ceased when the third arrives. And thus there will only be one bright line, that from the second coincidence. In this way (as the Committee point out) there may be either one or two bright lines for the same duration of spark. But if the duration of the spark be greater than that now spoken of, it will be comprised between two numbers that are easily determined, the difference of which is equal to the time elapsing between two successive coincidences. A very close approximation may be arrived at, and the inventors of the method show that, in virtue of the above mentioned probability of coincidence, by noting the total number of lines observed from a given number of sparks, and the velocity of rotation, the duration of the spark may be pretty accurately determined.

We cannot see at the same time more than a limited number of coincidence lines, so that if they exceed five or six, the velocity of rotation ought to be diminished.

By duration of the visible spark is to be understood the time elapsing between the first instant at which the spark commences, and the instant when, owing to a diminution in luminous intensity, it ceases to illuminate sufficiently the lines of the apparatus, so as to give a sensible image to the observer. The entire duration may be much greater.

The Committee further remark, that the duration of the spark being determined by the number of coincidences seen by the observer, if the degree of illumination of the lines were much diminished, it is to be feared that the number of coincidences would not diminish equally, in consequence of the enfeeblement of the light corresponding to the end of the discharge. And they think it would be of use to ascertain the effect of variations in luminous intensity, as in discharge between electrodes of various metals, placed at different distances, in gases at different pressures.

The proposers of the method have not been able to make appreciable the duration of a spark from an ordinary machine; but they found the duration of the discharges of condensers varies with the surface of these, with their arrangement and the resistance of the circuit. It varies also with the striking distance, the nature of the balls, and the humidity of of the air. In general, the duration increases with the condensing surface, and with the distance between the balls, and diminishes with the length of the circuit.

The limits of duration, given by their observations, are four-millionths of a second, and eighty-six-millionths of a second—with a possible error of one-millionth of a second.

FORMATION OF STANDARD MEASURES IN ELECTRICAL QUANTITIES.

[Translated from the Journal des Telegraphes.]

The improvements recently made in Telegraphy have brought this branch of science to such a point of perfection that it is deemed necessary to adopt general and definite measures in the calculation of resistances, and other electrical estimates, in order to substitute a stricter language and more precise data to the quackish rules and hypotheses of former years.

Several standards of resistance are still in practice, which almost unexceptionably spring from arbitrary estimates, allowing nothing beyond a bare comparison with similar quantities.

In England, America, East India and Australia, a system of definite standards has been generally adhered to, which we propose to examine briefly by presenting a summary of the investigations, entitled "Committee on Electrical Standards," made by the Board of the British Association for the Progress of Sciences, and also of the reports published on the same subject by Messrs. Ferguson, Fleming Jenkin, and Latimer Clark.

Weber and Thomson were the first in proposing a system enabling the calculator to express electric quantities in positive standards, which they selected precisely because of the connections existing reciprocally between them and the standards of power and work, which henceforward ought to be accepted as the universal link of all physical standards.

Mr. Jenkin presented the original idea of this system in his sketch on the electric instruments exhibited at the International World Fair of 1862.

"A battery or rheomotor of a standard electro-"motive power will generate a current of standard "power in a circuit of standard resistance, and "through this circuit it will convey, in the standard "of time a standard quantity of electricity which "will perform, during the same time, a standard of "work or its equivalent. As these relations do not "determine the complete magnitude of the serie of "standards, Weber proposed several ways of ob-"taining this serie; but as standards are used which "are taken from observations on the magnet, the "most expedient will probably be found to be that "which allows to determine the serie by means of "the definition of standard of current, in which case "the standard is that of a current, the standard "length of which imparts from the standard of dis-"tance a standard of power on the standard of the "magnetic pole. As for the definition of the stand-"ard of the magnetic pole proposed by Gauss and "Weber, it depends entirely upon the standards of "volume, length and time."

Mr. Ferguson gives the following definition of the standard of current: The standard of current, says he, is that which, in a wire measuring one metre, forming an arc having a radius of one metre, or, which is the same thing, an arc of 57¼ degrees, would repel a standard pole to the centre of the circle with a standard power. The whole circumference of a circle having a radius of one meter is 6m. 2832; it would consequently repel a pole of 6.2832 standards of power. If the circle were placed in the magnetic meridian, the deviation shown by a little animated needle situated in its centre, as practiced with the galvanometer of tangents, would be determined by the whole circumference, so that the force of the current, calculated only on one metre of that circumference, enters but for $\frac{1}{6.2832}$ part in the deflective force. In a straight wire one metre long, the standard current repels a similar standard to a distance of one metre with a standard force. A standard magnetic ground repels, with a standard of force, a standard current of one metre, kept up at right angles with the line of magnetic forces; consequently, in a standard magnetic ground, one metre of standard current, forming an arc of 57¼ degrees, and kept up in the magnetic meridian, would produce a deviation of 45 degrees on a small animated needle placed in its centre.

Thus, in determining the standard of electric resistance and other quantities of the same kind, the only thing to be done is to adhere to the natural congruities existing between them and the fundamental standards of time, volume and space.

In the electro-magnetic system of Weber and Thomson the following equations are deducted from the relations between the electric and mechanical standards: $W = C^2 R t$ in which W is the work performed during the time t, by a current C, through a conductor of resistance R. Such are the laws of Joule and Thomson.

On the other hand Ohm gives the following law: $C = \frac{E}{R}$ wherein E expressed the electro-motor power; and we possess likewise an original relation offered by Faraday in the formula $Q = C t$, where Q is the sum of electricity conveyed and neutralized in the time t by current C.

Finally, the whole system is made definite by the application of the law of Gauss, the terms of which require that the standard of length of the standard of current will produce the standard of power on the standard of pole from the standard of distance.

If, dismissing the idea of magnetism, this last definition may be expressed as follows: The standard of current—passing circularly through two circles of an area standard, disposed in vertical plans and at right angles respectively, provided one of the two circuits be at a great distance D above the other—will determine between the circuits or couple the magnitude of which will equal the converse of the cube of the distance D. This last relation expresses the proposition made by Weber for the concatenation of electric and magnetic standards.

With the help of these relations the four magnitudes, R C Q and E are determined without resorting to any other standards but those of time, volume and space, and when reduced to these fundamental standards it is made manifest that the quantity expressed by R represents only a velocity, that is, the quotient of the length by the time.

This is the reason why the definite standard of resistance is represented by $\frac{\text{metre}}{\text{seconde}}$ in the same manner as the common and indefinite standard of work is expressed under the designation of kilogrammetre or metregramme.

It is difficult to give a common-place definition of what a standard is, but the following explanation presented by Mr. Jenkin will show how an actual velocity can be resorted to in measuring a resistance by using the velocity with which in some instances it is necessary to put in motion a part of a circuit in order to induce a given current into the circuit, the resistance of which is to be calculated.

"The resistance of the definite $\frac{\text{metre}}{\text{seconde}}$ is such "that a current produced in a circle possessing "of such a resistance imparted by the electro-mag-"netic force of a straight rod of one metre in length, "moving in a magnetic ground of standard intensi-"ty, perpendicularly to the lines of force and to its "own direction, with a velocity of one metre in a "second, and accomplishing no work or equivalent "of work, would determine, in that circuit and in "one second, a total quantity of heat equivalent to a "definite unity of work, or, according to Joule's "experiments, enough caloric to increase by one de-"gree centigrade the temperature of 0.0002405 "grammes of water to its maximum of density."

Thus the relations, either between quantities called by Weber electro-magnetic standards, or those existing between those quantities and ordinary mechanical standards may be recapitulated as follows:

The standard of current conveys a standard of electricity through a standard circuit in the standard of time.

The standard of current running through a standard conductor of length will impress a standard of force on the standard pole, from the standard distance.

The standard of current in a standard conductor of length produces an effect equivalent to the standard of work during the standard of time.

The standard of current will be produced in a standard circuit of resistance by the standard of electro-magnetic force.

We will not examine here the contrivances put in practice by Weber and the British Association Committee to ascertain the exact measure of the resistance of a wire.

The standards of resistance of the British Association are composed of an unalterable alloy of platinum and silver representing a very near approximation to 10,000,000 $\frac{\text{metres}}{\text{secondes}}$ of Weber's definite electro-magnetic system. The *unit* $\frac{\text{metre}}{\text{seconde}}$ being too unimportant for practice it was agreed on that no designation implying an idea of definite quantity would be given to this standard, and it received accordingly the name of ohm or ohmad, in order that, if subsequently better methods of determination should be devised, this standard might be used, by adding thereto a simple co-efficient, in reducing to definite measures those taken in ohms.

The standards of resistance of the dielectric are known as megohms of one million of ohms each, one microhm being the $\frac{1}{1000000}$ part of an ohm.

The standard of tension or electro-motor power is called volt, and according to a late determination of Professor Sir William Thomson is equal to 1,004 of tension of one of Daniell's elements. One million of volts form a megavolt, and the microvolt is $\frac{1}{1000000}$ of the volt, which is equal to 100,000 definite electro-magnetic standards of tension.

The standard of quantity is the farad, divided into microfarads. One megafarad contains one million of farads.

The farad is that quantity of electricity which would, with an electro-motor power of one volt, overcome in one second the resistance of one megohm, and as these quantities vary in inverse ratio of the resistance, a megafarad would overcome the resistance of one ohm in one second.

The farad is the 100,000,000th part of a definite electro-magnetic standard of quantity, and the megafarad $\frac{1}{100}$ of same.

The standard of current of the British Association is a current of one farad per second (that has sometimes been called galvat), or that which would run: with the tension of one volt, through the resistance of one megohm, or with the tension of one microvolt through the standard of resistance. It is equivalent to the $\frac{1}{10000000}$ of the natural electro-magnetic standard of current, or to the standard of tension through the standard of resistance.

The standard of power in metrical measures is that which has produced a velocity of one metre in one second in a volume weighing one gramme, after an action of one second on that volume. As gravity alone imparts a velocity of 9m. 808 per second to one gramme weight, it follows that the natural

Digitized by Google

standard of work is the effort which is necessary to put in motion $\frac{1}{9808}$ of one gramme to a distance of one metre in one second.

The conventional standard of work, W, generally used in metrical measures is, however, the effort wanted to run up a weight of one gramme to a height of one metre, and is called metre-gramme. Consequently, it is equal to 9,808 definite standards of work. The electrical work is equivalent to the quantity of work performed in one second multiplied by the depression of tension, or difference of potential, varying thus as the number of farads multiplied by that of volts. The exact standard of work is equal to 1,000 volts-farads, and the metre-gramme or conventional standard to 9.808 volt-farads per second, or 9,808 farads descending in one second from one volt of tension.

From the above it is made manifest that the system of electrical measures adopted in England is definite, and rests on natural and invariable bases instead of being deducted from arbitrary quantities having no connection between them. This coherent and rational system contributed powerfully to the present advance of the electric science, and there is no doubt that before long it will be put in practice everywhere.

CORRESPONDENCE.

To the Editor of the Journal of the Telegraph:

Will you allow me space to enquire whether outsiders can be admitted to your Insurance Organization? Why not? You have the machinery in operation, and evidence enough that the plan is a good one. Will you let book-keepers, for instance, into membership? If so, your membership might reach thousands, which would be mutually beneficial to your own employés, and others uniting with them.

I. C.

Answer:—"Outsiders" are not eligible to membership. The Association was formed for the benefit of telegraphers only. The amount of labor required to carry on the affairs of the Association as it is, is quite large, and would be increased to a serious burden by the plan suggested.

W. J. Mathews is informed that he can be supplied with bound volumes, Nos. 3 and 4 of the Journal, and with the back numbers of the current volume, also with sets nearly complete of vols. 1 and 2. Price, for bound volumes, two dollars per copy.

W. K. Applebaugh, 145 Broadway, New York, is the Secretary of the Telegraphers Life Insurance Association. Apply through him.

There are ten words in the following:

"Draft matures Saturday. Bergfeld won't recall unless protested for non-payment."

There are ten words in the following message. In all such cases the figures are to be counted exactly as expressed in the words.

"Want to go south eight-thirty, (8:30) this evening."

FOREIGN TELEGRAPHIC ITEMS

THE WEST INDIES AND PANAMA CABLE EXPEDITION.

From Kingston, Jamaica, under date of August 10, by the steamship Rising Star, we have the following news report:

"Sir Charles Bright, the electrician, arrived here in the British mail packet from Southampton, to look after the wire covered cable between this city and Aspinwall. The cable fleet arrived in Kingston reporting the loss of the greater part of their grappling gear, and without any favorable tidings of the lost cable. After coaling and undergoing some repairs the vessel will return to the search, this time under the direction of Sir Charles Bright himself. Mr. Edward Bright returns to England on important business.

"It is reported that the Great Western Telegraph Company, to complete their West India and South American arrangements, have decided upon running a line of cable from St. Thomas direct to Aspinwall, St. Thomas being connected with another line of cable to the Island of Bermuda, which connects with New York on the one hand and England on the other. Messages are to be sent at the rate of twenty words for twenty shillings."

By royal decree the Platino-Brazileira Telegraphic Company has obtained authorization to operate in the empire, and approval of the statutes. The company is formed to carry out the Lamas telegraph concessions from the Argentine and Oriental Governments, with power to contract with the Brazilian Government for connecting the Argentine and Oriental lines with those of Brazil, and to purchase the Lamas concession for telegraph cable between Rio Janeiro and Montevideo.

The London *Railway News* under date of August 9, says:

"The tendency of prices in Telegraph Shares has been towards lower values, and the dealings have not been numerous. Anglo-American have fallen 1 to 2 per cent.; British Australian, ¼; British Indian Extension, ⅜; China Submarine, ⅛; Mediterranean Extension, ¼; Société Transatlantique Français, ¼ to ½; Submarine, 5; West India and Panama, ¼. The fall in the price of these securities is unaccountable. The business of the submarine telegraphs continues very large, and the companies are not subject to any of the advances in the price of materials which affects railway property.

The practice hitherto in vogue by the German State Telegraphs of counting the two words, "*via* Amsterdam," as an integral part of a message sent to France or any other country over the Dutch lines, or "*via* Southampton," if sent to Gibraltar, Spain, Portugal and America, through England, has created much discontent and grumbling, as it really has nothing to do with the actual contents of a telegram, which, with its limited number of words, and even the most acutely considered mode of packing, is found to cost quite money enough without the deduction of two words intended simply to indicate to the officials the route selected, and which are always suppressed in the telegram as delivered to the recipient. It has, therefore, caused great satisfaction to find that on the urgent representation of the Hamburg Chamber of Commerce, the Director-General of the Telegraphs has gracefully given way to the public wish, and issued orders to the subordinate officials of his department no longer to count the two words in question, which in the future are only to be written in parentheses on the margin, and not charged.

From Queensland we learn that telegraphic communication continues to extend notwithstanding political fixation. Tenders have been voted for an extension from the Burdekin River to Ravenswood. The line from Cardwell to the Gulf of Carpentaria (393 miles) was opened on the 3d of January last; it is, therefore, ready for union with the cable from Java. There is a proposition now before Government, with respect to that same cable communication, which will be likely to obtain more favor than the South Australian scheme. With the exception of the communication between Java and Port Darwin, arrangements are perfected for complete telegraphic intercourse with Europe. The line by Queensland is considered, for practical purposes, far safer and more easily maintained than the South Australian line, which is on the point of being completed.

Telegraphic despatches are now received in South Australia nine days from London.

The total number of messages forwarded from English postal telegraph stations during the week ending August 3, 1872, was 330,590—an increase over the corresponding week of the previous year of 77,455.

The total number of messages forwarded from Postal Telegraph Stations in the United Kingdom during the week ending August 10th, 1872, was 320,555, and during the corresponding week of 1871, 251,898; showing an increase in the week of 1872 on that of 1871, of 68,657 messages.

The receipts of the Great Northern Telegraph, on their European lines, during July were 124,293fr. (£4,922), against 105,385fr. (£4,216) in July, 1871—showing an increase of 18,808fr. (£756).

It is reported that a line of telegraph cable has been arranged for to be laid between the island of Jamaica and Belize, the capital of British Honduras.

HYDRO-ELECTRIC CABLE.

Experiments are continuing with this new invention of M. Tomasi, 69 Avenue de l'Alma, Paris, which depends upon undulations in a fluid vein confined in a copper tube, and which, it is said, is about to be practically applied. The latest result reported is that the inventor has succeeded in dividing the pressure exercised at the outset into and distinguishing the two parts—one belonging to the receiving apparatus, which is constant, and the other appertaining to the cable or transmitting fluid. The latter is weak, not exceeding the third of an atmosphere per kilometre, and is variable in direct proportion, apparently, to the length of the cable. Hence the pressure to be exerted does not exceed practicable limits.

The Academy of Sciences in Bologna has announced that a prize of 1,200 *lire* ($240), the "Aldini Prize," will be awarded to the author of the best scientific experimental essay on galvanism or dynamic electricity. Essays intended for the competition must be sent in between July 1, 1872, and June 30, 1874, and must be written in Italian, Latin, or French. They must be either written or printed; but, in the latter case, must not have been published previously to the two years above mentioned. Each essay is to bear a motto, and to be accompanied with an envelope stating the name of the author. They must be addressed to the Perpetual Secretary of the Academy of Sciences of the Bologna Institution.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory and Province on the Continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JOURNAL OF THE TELEGRAPH,

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, SEPTEMBER 2, 1872.

UNIFORM RATE FOR THE TRANSMISSION OF TELEGRAMS.

A great deal has been said in regard to the beneficial results which are claimed to have attended the working of the Montreal Telegraph Company's lines during the past year, on a uniform 25-cent rate, throughout the territory covered by them, in place of a moderately high tariff regulated according to distance. The inference naturally drawn from the statements made, was, that the change in the tariff had effected a material average reduction in the charges, and that this reduction had been more than compensated for by the increase in the traffic. Now let us examine the facts and see if there is really anything exceptional in the experience of that company which can be usefully adopted by ours, or which shall tend to show any different result, in telegraphic economy, than that hitherto developed.

The following official statement of the operation of the Montreal Telegraph Company for the years 1870 and 1871, will serve to show the results of the new and old tariffs:

Number of messages sent in 1871	1,259,653
Do. do. 1870	1,006,102
Increase in 1871 (about 25 per cent)	253,551
Gross receipts in 1871	$392,687 20
Do 1870	362,865 39
Increase in 1871 (about 8 per cent)	$ 29,821 81
Expenses in 1871	$242,890 83
Do. 1870	208,907 84
Increase in 1871 (about 15 per cent)	$ 33,482 99
Net profit in 1870	$153,957 56
Do. 1871	150,296 37
Decrease in 1871 (about 2½ per cent)	$ 3,661 18
Average tariff in 1870	36 cents.
Do. 1871	31 1-10 do.
Average reduction (about 13 per cent)	4 9-10 do.
Number of miles of wire in operation in 1871	14,337
Do. do. do. 1870	11,783
Increase in 1871 (about 21 per cent)	2,554
Number of offices in operation in 1871	805
Do. do. 1870	675
Increase in 1871 (about 19 per cent)	130

There was an increase in 1871 over 1870 in every item of expense, but largest in that of salaries which—

For 1871 was	$158,529 39
And in 1870	131,943 43
Increase in 1871 (about 20 per cent)	$ 26,585 96

Thus we find that the change in the tariffs only resulted in a reduction of $4\frac{3}{16}$ cents on each message, and that the effect of this reduction was to decrease the net profits as compared with the year previous, about 2½ per cent.

On the first of October, 1869, the Western Union Company made an average reduction in rates of about 15 per cent. This was followed in the succeeding month by a decrease in the gross receipts as compared with the same month of the preceding year of $41,385 07, accompanied by an increase in the current expenses of $26,929 26, making a difference in the net profits of $68,314 33. On the first of January, 1870, the new half rate tariff for messages sent at night went into operation; the result of which was a decrease in the gross receipts of $62,113 21, and an increase in the expenses of $58,452 38, making a decrease in the net profits as compared with the corresponding month of the previous year of $120,565 59. Then October 1, 1869, when the reduced tariff went in operation, to May 1, 1870, a period of seven months, the gross receipts were $233,273 less and the expenditures $186,019 more than for the same months of the preceding year, making a difference in the net earnings of $419,293.

It has taken this Company two years of time, and has required the erection of over 20,000 additional miles of wire, to so increase its traffic under the reduced tariff as to yield as large a net revenue as it enjoyed previous to the reduction in 1869.

These facts demonstrate very conclusively that an increase in the amount of traffic in the telegraph business requires a corresponding increase in the wires and operators, and that the per centage of expense increases very approximately to the increase in the number of messages transmitted.

INFORMATION FOR MANAGERS.

New Tariff Books are now being sent out. All offices will soon be supplied. The offices are arranged alphabetically, by States. This will greatly facilitate the finding of offices where there are many of the same name. As soon as these books come into use, it is desired that the postings from the Tariff Circular in the JOURNAL shall be made at once, at every issue. This is important. Were this done promptly and correctly, no errors in rates would occur. Hereafter, ignorance in these matters will be deemed inexcusable.

Red messages must be held until full rate and press business is out of the way. The object is two-fold; to give important business better facilities, and to occupy the wires *at night*. Red messages on the hooks in the morning should be got off early. Offices which do not answer calls promptly in the morning, should be reported to the superintendent at once.

WESTERN UNION TELEGRAPH COMPANY,
TREASURER'S OFFICE,
NEW YORK, August 20, 1871.

To all Managers of W. U. Offices:

Drafts remitted to this office should be made payable to the order of R. H. ROCHESTER, TREASURER.

Great inconvenience is caused by the omission of the word "Treasurer."

R. H. ROCHESTER, Treasurer.

INFORMATION WANTED.

Can any of our readers inform us why the consumption of the number 1 (ordinary receiving) blank exceeds that of the number 2 (ordinary counter) blank by fully ten per cent? Also, why the consumption of number 44 (red receiving) is fourteen per cent. in excess of number 45 (red counter) blanks. Statistics show this to be the case.

The discrepancy between the consumption of the ordinary blanks can partially be accounted for in the fact that large numbers of telegrams upon railroad service, as well as messages relating to our own service, are not written upon the printed form, while answers which may be received are generally written upon the number 1 blanks. Yet this cannot account for all of the difference, especially when the enormous waste of the counter blank is taken into consideration.

The large discrepancy between the red blanks is the more remarkable inasmuch as nothing is received upon the receiving blanks but its legitimate business. Considering the waste of the counter blank, the consumption of the receiving blank should be less than that of the former, instead of, as it is, fourteen per cent. in excess.

WE have received from the artist, Mr. A. B. Greene of St. Louis, a photographic copy of his picture entitled "Neglect of Duty," together with a circular of description, testimonials, &c. The picture is so suggestive in itself that no description seems necessary to accompany it.

The subject is one that has never before been illustrated, and this design, portraying as it does a *moral* that concerns *all telegraph operators*, particularly those connected with the running of trains, has been received with such enthusiasm and encouraging encomiums by all railroad men and others who have seen it, that the artist (an operator for many years) has been induced to have it duplicated by photographing and circulated.

The picture represents, in the foreground, a train dispatcher or operator having fallen asleep in his chair; in the upper background, as a possible consequence, the collision and destruction of two trains, while Death stalks in from the right to complete the scene.

This little work is really excellent, and its influence for good will readily be felt by those who are so fortunate as to see it. We hope and believe that these copies will meet with a large and rapid sale.

A PLEASANT little affair was that which occurred a couple of weeks since, when Mr. T. C. Harvey, Train Dispatcher of the Clarksville Division of the Louisville and Nashville and Memphis and Louisville Railroad, was presented by the operators under his supervision with a set of nickel plated telegraph instruments. While, on principle, we are not in favor of presentations from subordinates to superiors, yet we can see how gratifying such an occurrence must be to one who really has the welfare and interests at heart of those under him. Mr. Harvey is to be congratulated in possessing these qualities, and also in being associated with men who can appreciate them.

Digitized by Google

A CALLED meeting of the telegraph operators along the line of the Kentucky Central Railroad was held on the evening of August 15th, 1872, for the purpose of expressing their sympathies in regard to the death of their fellow-operator, James E. Woodruff.

The meeting was called to order by J. S. Lyle at 7½ P. M.

C. W. Caton was elected chairman and A. Bishop secretary.

A motion was made that the chair appoint a committee to draft resolutions. The committee consisted of J. S. Lyle, J. E. Pogue and J. T. Sharrard, who reported as follows:

WHEREAS, It has pleased Almighty God to remove from our midst our late young friend and fellow-operator, James E. Woodruff,

Resolved, That in his death we mourn the loss of a highly esteemed friend, an able and trustworthy fellow-worker and a kind and genial companion, whose good character and deportment has ever commanded our respect and esteem.

Resolved, That we tender to the bereaved family of the deceased our heartfelt sympathy in this their hour of affliction.

Resolved, That a copy of these resolutions be sent to the JOURNAL OF THE TELEGRAPH for publication.

J. E. POGUE,
J. T. SHARRARD,
J. S. LYLE.

Motion was then made and carried that the chair appoint a committee of two to present a copy of these resolutions to the family of the deceased, and that they also be printed in the Cynthiana and Lexington papers.

The meeting then adjourned.

C. W. CATON, Chairman.

A. BISHOP, Secretary.

WE have received a number of replies in answer to our request in the JOURNAL of August 1, for information as to the whereabouts of Mr. Charles H. Hubbard. He is reported as being in St. Louis, in Charleston, S. C., in Towanda, Pa., and in Memphis, Tenn., all at or about the same time. Is Mr. Hubbard ubiquitous?

We are obliged to our friends for answering so promptly.

THE lower classes in Japan are afraid of the telegraph. They cannot altogether see "how the old thing works," and they are simple enough to think that it is the device of the devil, and that the wires are coated with the blood of young women, and that the census now being taken is for the sole purpose of finding out the number of available Japanese maidens whose blood will do for telegraphic purposes. The idea is a curious one, and it is strange that the Japanese should not understand the explanation.

ELECTRICAL WONDERS.

By the mirror galvanometer of Sir William Thomson, which was of the utmost importance in securing the success of the Atlantic Cable, a ray of light is reflected from a minute mirror that is attached to a magnetic needle. When the electric current passes the magnet is deflected, and the movement of the reflected spot of light over a scale indicates the resistance to the passage of the current. The united weight of mirror and magnet is three-quarters of a grain.

During the experiments with the Atlantic Telegraph both cables were connected at the American end, giving a circuit of more than four thousand miles, yet a current passed through the whole distance in less time than a person could pass across the small room in which the experiment was made—and, most wonderful of all, the battery that accomplished this result was contained in a lady's silver thimble.—*Scribner's for September.*

WE find the following letter from President Orton, in the New York *Tribune* of August 13. Mr. Orton tells the gratifying story so completely that no comment is needed:

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
NEW YORK, August 12, 1872.

To the Editor of the Tribune:

SIR:—I find the following in the Money Article of the *Tribune* this morning:

"The most decided fall was in Western Union "Telegraph, which was selected as the special object "of attack, and was pushed down to 70⅛—a fall of "4½ per cent. The depression in this stock is at- "tributed to the rumored failure of the Company to "negotiate their real estate bonds in the London "market, and the alleged necessity of the sale of "the Company's stock to provide the means for the "construction of the new building, to be erected on "Broadway in this city."

Concerning this rumor, permit me to state:

First: The bonds of this Company for $1,500,000, issued for the purpose of providing funds wherewith to pay for the land and the erection of a building thereon, at the corner of Broadway and Dey streets, in this city, were sold and delivered to, and paid for by a London house in June last, at par, in currency.

Secondly: As payment has already been made for the land, and the remainder of the proceeds of the bonds is ample for the erection of the building upon the plans adopted, "the alleged necessity of the sale "of the Company's stock to provide the means for "the construction of the new building," does not exist. Not one share of the stock purchased for account of the Company has been, or will be sold.

The Managers of this Company have never had so many and so substantial reasons for being satisfied with the condition of its affairs, and with the prospects for the future, as at the present time. Its revenues, gross and net, are larger than ever before, and the evidences are abundant that the increase of both in the immediate future will be greater than during any corresponding period in the past.

Very Respectfully,

(Signed.) WILLIAM ORTON, President.

IMPORTANT TELEGRAPH EXTENSION.—The Western Union Telegraph Company has just completed the extension of its lines to the Straits of Mackinaw. This means of speedy communication will prove a matter of great importance to the marine interests of the lakes, and supplies a want that has heretofore been sorely felt by vessel owners and insurance companies. Offices have been established at Cheboygan, Duncan City and Crawford's Quarry, and one will be opened in a few days on the dock at Old Mackinaw. Messages for Mackinaw Island may be sent over daily by boat from Cheboygan or Old Mackinaw.

ELECTRIC LIGHT.—The Alliance Company, at Paris, are now manufacturing improved magneto-electric machines for the electric light. These are now made with four disks, and supply from 230 to 300 careel jet burners, with a speed of 350 revolutions per minute, and driven by a 2½ horse power steam engine. The machines certainly seem expensive, costing £320 each; but it is estimated that thereby the combustion of a few pounds of charcoal gives an illuminating effect equal to that of 25 pounds of colza oil. This mode of illumination, therefore, is ultimately inexpensive, especially when applied on the large scale, for ships, large halls, light-houses, &c., for which it is well adapted; and we shall, no doubt, soon hear of new applications of the invention.

TARIFF BUREAU.

SENI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York.
September 1, 1872.

To all Offices on W. U. Lines:

The following changes in tariff have occurred since August 15, the date of the last tariff order.

Managers are hereby required to enter these changes in their tariff books as soon after the receipt of the JOURNAL *as possible:*

NEW OFFICES.

59 Angora, Pa.
289 Boswell, Ind.
Bridgeport, Cal., tariff same as Napa City, Cal.
304 Bellevue, Ala.
* Cumminsville, O.
Crawfords Quarry, Mich., tariff 10 cents more than Alpena, Mich.
Cheboygan, Mich., tariff 20 cents more than Alpena, Mich.
* Chestertown, Md.
* Cromwell, Conn.
456 Doniphan, Kansas.
25 East Brookfield, Mass., re-opened.
140 Fairview, Butler Co., Pa.
175 Graniteville, S. C.
67 Hopewell Cross Roads, Md.
242 Hughes Sta., O.
465 Iowa Point, Ks.
142 Jordan Bridge, Alum Springs, Va,
* Kennedyville, Md.
10 Kingsman, Me., c'k Bangor, Me.
304 Macon Sta., Ala.
* Massey's Cross Roads, Md.
150 Mooreheads, Pa.
270 Marcellus, Mich.
357 North Henderson, Ill.
231 North Adams, Mich.
181 Point Pleasant, O.
233 Sharon, O.
465 White Cloud, Ks.
10 Winn, Me., c'k Bangor, Me.

NEW OFFICES ON OTHER LINES.

	Tariff for Other Lines.		*Leaves this Line.*
Chestertown, Md.	40	3	Townsend, Del.
Cromwell, Conn.	30	3	Hartford, Conn.
Cumminsville, O.	25	2	Cincinnati, O.
	60	4	Chillicothe, O.
	75	5	Marietta, O.
Kennedyville, Md.	30	2	Townsend, Del.
Massey's Cross Roads, Md.	25	2	Townsend, Del.

OFFICES CLOSED.

Belpre, O.; Cunningham, Mo.; Darlington, Md.; Lavacca, Tex.; Otterbien. Ind., and Port Lavacca, Tex.

GENERAL INFORMATION.

On and after September 1st, 1872, no "half rate" messages will be taken for, or received from, offices on the International Ocean Telegraph line in Florida. The offices of this Company are those whose business "leaves this line" at Lake City, Fla.

Hereafter business for Lincoln, Mattawamkeag, Oldtown, Vanceboro and Danforth, Me., will be checked direct.

WILLIAM ORTON,
President.

TELEGRAPH PROJECT IN WASHINGTON TERRITORY.—J. W. Sweeney recently started the project of constructing a telegraph line from Seattle to Port Townsend, *via* Freeport, Pt. Blakely, Pt. Madison, Pt. Gamble and Pt. Ludlow, and articles have been filed—capital $25,000. The canvass for subscriptions has proved highly successful, 104 shares being taken at Pt. Townsend alone; and at the other points such encouragements have been given as assure completion of the line, which is expected within three months.—*Chicago Railway Review.*

BORN.

WHIPPLE.—At Hightstown, N. J., August 14, 1872, to Thomas D. Whipple, lineman W. U. Tel. Co., a daughter.

MARRIED.

DE LONG—THOMAS.—At Shreve, O., August 17, 1872, by Rev. J. C. Gillem, W. H. De Long, operator P., F. W. and C. Railway, to Miss Josie E. Thomas, Manager W. U. Tel. Office, Shreve, O.

HILTON—LOUNT.—At Bay City, Mich., August 11, 1872, A. M Hilton, Manager W. U. Tel. Office, Kawkawlin, Mich., to Miss Sade A. Lount. of Kawkawlin.

WATKINS—CARNEY.—August 15, 1872, at the residence of the bride's father, by Rev. J. W. Emery, M. F. Watkins, Manager W. U. Tel. Office, Burns, N. Y., to Miss Hily A. Carney, of Burns.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 20. NEW YORK, SEPTEMBER 16, 1872. WHOLE NO. 117.

REFLECTING GALVANOMETERS.

Ampere suggested, as early as the year 1820, the employment of a galvanometer for the purpose of telegraphing, and in 1833 Gauss and Weber used a reflecting galvanometer as an indicator upon a line about one mile in length, uniting the Observatory and Physical Cabinet at Gottingen. Their alphabet was made up of combinations of right and left deflections. This apparatus, the first ever employed for practical telegraphy, has lately, in the hands of Professor Sir William Thomson, become the most sensitive of all telegraphic instruments. His reflecting galvanometer is the only instrument at present by which a cable, 2,000 miles in length, can be worked by a battery of low tension. It consists of a needle formed of a piece of watch spring three-eighths of an inch in length. The needle is suspended by a thread of cocoon silk without torsion. The needle lies in the centre of an exceedingly delicate galvanometer coil. A circular mirror of silvered glass is fixed to the needle, and reflects at right angles to it in the plane of its motion. It is so curved that when the light of a lamp is thrown through a fine slit on it, the image of the slit is reflected on a scale about three feet off, placed a little above the front of the flame. Deflections to the extent of half an inch along any part of the scale are sufficient for one signal. In so delicate an instrument, the sluggish swing of the needle in finally settling into any position would destroy its usefulness. To rectify this, a strong magnet, about eight inches long, and bent concave to the instrument, is made to slide up and down a rod placed in the line of the suspending thread above the instrument. This magnet can be easily shifted as necessity may require. The oscillations of the needle due to itself are, by the aid of the strong magnet, made so sudden and short as only to broaden the spot of light.

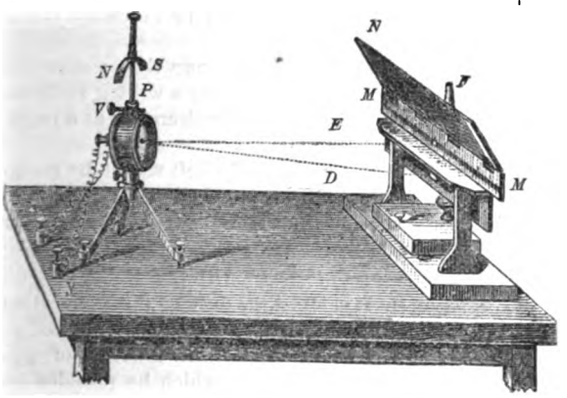

Fig. 1.

The above illustration, fig 1, shows the construction of the instrument: The galvanometer P contains the multiplication wire divided into several layers, and so arranged that it can be used for weak or strong currents, according to the requirements of the instrument. In the centre of the coil the magnetic needle is suspended, to which is attached the tiny mirror, and close before it is to be found a small collective lens, whereof the focal point lies almost in the mirror, in order to produce a sharp figure of the prism on the scale. The magnetic needle has a length of three-eighths of an inch, a breadth of one-twelfth of an inch, and a thickness of one-twelfth of an inch. The mirror connected with the needle has a thickness of only one two-hundred-and-fortieth of an inch. The magnetic needle is made from a small piece of a very fine watch spring, and the little mirror from one of the thinnest microscopic cover glasses. The magnetic needle and mirror used for signalling across the Atlantic weigh only one and one-half grains.

The entire box which encloses these parts is hermetically closed. The ends of the multiplicator wires are soldered inside the box to two screw posts, *x y*, wherewith the instrument is connected with the cable.

A curved steel magnet, N S, is fixed to a brass bar, P, in such a way that by turning the micrometer screw V, any required removal, upwards or downwards, or to the right or left, can be given to it, and by this means the magnetic needle, when in a state of rest, is kept in such a position that the picture of the slit D, which is reflected from the middle of the mirror, and likewise returns through the lens, appears upon the zero mark of the scale M M.

Opposite the galvanometer, the scale M M and the lamp F are to be seen. The light from the lamp penetrates through the slit D in an oblique direction to the looking glass, and is thrown back from it to the scale, somewhat upwards, in the direction E, where the picture of the slit is to be seen as a fine light line. The screen N can be turned up, and serves to keep the lamp-light from the scale. The instrument is necessarily used in a darkened room.

Thomson's Marine Galvanometer (fig. 2), is a reflecting galvanometer, constructed in such a manner that even the strongest rockings of a vessel wherein they are used cannot change the relative position of the small mirror towards the scale. For this purpose the magnetic bar *a* is fixed by means of three cocoon threads, at the top as well as at the bottom, to the little wooden frames A B, which carry the convolutions of wire. The cocoon threads pass accurately through the joint centre of gravity both of the magnetic bar and the mirror, so that when the multiplicator wire is turned the latter remains unaltered in its relative position to the layers of wire. The influence of the ground is thus prevented from affecting the instrument, and the magnet retains, under any changes of the instrument, the same position towards the scale which is attached to it on the same table board.

It is not less important for such a purpose to have the influence of terrestrial magnetism on the magnet destroyed. And this is attained by enclosing the multiplicator wire, with magnet *a*, looking glass and lens L, in a box made of strong soft iron, and at the same time putting up in the inside of the box a moderately strong, horse-shoe-shaped steel magnet N S, in such a manner that both its poles take hold of the rolls of wire. The magnetic action of these poles on the magnetic needle being stronger than the attractive power of the earth, the latter is neutralized by it, and the suspended needle is maintained in the position of rest under all changes in the situation of the instrument.

The small mirror is replaced by a small biconvex lens of 2½ feet focal distance, the back of it being silver plated, and forming at the same time a small concave mirror which reflects the falling rays in convergent directions, and concentrates them upon the scale. The curvatures of the lentiform looking glass are so calculated that the source of light is placed at a distance of about 1½ feet from the centre of the mirror, while the scale or the screen designed to receive the reflecting light is placed at a distance of eight feet from the focus. The screen is a flat piece of wood, covered by white paper, which is fixed on a black painted wall.

To avoid the disturbing movements of the light-shower on the screen, which are caused in consequence of the shaking and flickering of the flame, the lamp is enclosed in a cylindrical box, in which, on the side turned towards the mirror, is to be found a small slit, where the flame burns gently. When the galvanometer needle is at rest, the light-shower appears exactly on the middle of the screen in the form of a small quadrangle of ¾ of an inch in length and ¼ of an inch in breadth; when it is turned off this picture moves according to the deviation of the needle, to the right or the left, and produces in this way, as by the needle telegraph, two primitive signs, by the repeating and combining of which in groups an alphabet is constructed.

With such an arranged ship or marine galvanometer, all kinds of galvanometrical measurings can be done at sea even in very stormy weather, as readily

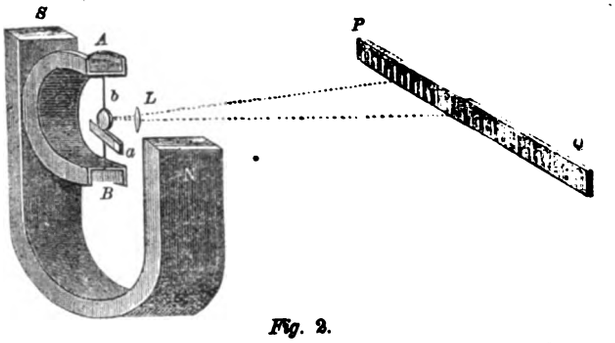

Fig. 2.

and surely as on terra firma—neither the ever changing course of the vessel nor the high running waves of the sea have any influence whatever on the movements of the light-shower.

It is easy to understand that the side—horse-shoe-shaped—magnet weakens in some degree the sensibility of the instrument; on that account, when use is made of instruments of this kind, in order to serve as cable-speaking instruments, a somewhat stronger current must be used than that required by the single reflecting galvanometer.

CONSTITUTION OF THE TELEGRAPHERS' ASSOCIATION.

ADOPTED JANUARY 15, 1872.

Preamble.

As a vital link in the chain of commercial intercourse, a powerful accessory to the advancement of civilization, and an indispensable agent of the supreme law of the land for the protection of life and property, the labors of the telegraphic profession stand second to none in the wide field of human industry. In this conviction we, the practical operators, to whose united skill the telegraphic system of America is indebted for its present development and success, actuated by a just feeling of pride in the future welfare and standing of our fraternity, have combined our efforts for the purpose of elevating to its proper standard the occupation which we have chosen as our means of livelihood. The nature of our business is such that a vast combination of capital must necessarily ever intervene between our most intelligent efforts and the commensurate reward of an appreciative public. We most earnestly discountenance strikes, as being detrimental to the interests of both employer and employé; but as a means of attaining our aim we seek to build up, as a protection against the aggressions of this powerful accumulation of capital, an organization of labor, founded upon well-defined principles, guided by well-directed counsels, and governed by intelligent legislation, which shall become equally powerful and equally worthy of respect. In order the more effectually to harmonize and direct our movements, the following Constitution has been adopted for our government.

CONSTITUTION.

General Organization.

ARTICLE I.

SECTION 1. This organization shall be known as the TELEGRAPHERS' ASSOCIATION.

SEC. 2. The Association shall be composed of independent divisions, designated as Councils, and known by their numbers alone.

SEC. 3. All power shall be vested in the Councils through their local organizations.

SEC. 4. For the better transaction of general business, one Council shall be designated as the Supreme Council, and intrusted with the performance of all duties incumbent upon that position.

ARTICLE II.

SECTION 1. The officers of the Supreme Council shall consist of a Supreme Councillor, a Supreme Vice-Councillor, and a Supreme Secretary.

SEC. 2. It shall be the duty of the Supreme Councillor to authorize the establishment of Councils, and assign to each Council its designating number, and to authorize the distribution of all books, pamphlets and circulars that may be placed in his charge for the general use of the Association.

SEC. 3. He shall have power to appoint such assistants, not elsewhere provided for, as he may require for the transaction of the legitimate business of the Supreme Council.

SEC. 4. It shall be the duty of the Supreme Vice-Councillor to perform all duties pertaining to the Supreme Council that may be required of him by the Supreme Councillor; and, in the absence of the latter, to assume the position of Supreme Councillor.

SEC. 5. It shall be the duty of the Supreme Secretary to keep a complete record of the location and designating number of each Council, the numbers of its members and the names of its officers; to keep a true account of the expenses of the Supreme Council, and to levy such assessments upon each Council as may be necessary to defray said expenses. He shall notify the Councillor of each existing Council of the formation of new Councils, the numbers by which they are designated, the names of their officers, and the location of their headquarters. He shall retain in his possession, during his term of office, all record books and such articles as may be designed for the use of the Supreme Council, and shall allow no person to have access thereto excepting the Supreme Councillor and Supreme Vice-Councillor. He shall be intrusted with the care of books, pamphlets and circulars intended for distribution, and shall issue the same only upon requisition by the Supreme Councillor; and at the expiration of his term of office he shall deliver to his successor all property belonging to the Supreme Council, and take a receipt therefor.

ARTICLE III.

SECTION 1. Council No. 1, under whose auspices this organization is founded, shall hold the position of Supreme Council for the term of one year, dating from the adoption of this Constitution. At the expiration of that time Council No. 2 shall succeed it in the position of Supreme Council for the term of one year, to be succeeded in turn by each Council of the entire Association for the same length of time, according to the rotation of their designating numbers.

SEC. 2. After the Council designated by the highest number shall have holden the position of Supreme Council for one year, Council No. 1 shall again assume that position, to be succeeded in rotation by each Council, as before.

SEC. 3. The regular rotation of Councils may be changed at any time, in order to promote the best interests of the Association, by a majority vote of two-thirds of the whole number of Councils.

ARTICLE IV.

SECTION 1. The Councillor and Vice-Councillor of any Council holding the position of Supreme Council shall assume the duties of Supreme Councillor and Supreme Vice-Councillor, respectively, for the term of one year.

SEC. 2. The Supreme Secretary shall be elected by ballot, by the Council which is about to succeed to the position of Supreme Council, at least fourteen days previous to its assumption of the duties of that position, and the Councillor of that Council shall immediately notify the Supreme Councillor of the result of said election.

SEC. 3. Thirty days previous to the expiration of the term of office of the Supreme Council, the Supreme Secretary shall notify the Councillor of the Council upon which the duties of the Supreme Council shall next devolve, that in the event of its succeeding to that position, a Supreme Secretary should be elected by that Council.

The Formation of Councils.

ARTICLE V.

SECTION 1. The location of the headquarters of each Council shall be approved by the Supreme Councillor.

SEC. 2. Each Council shall consist of nine or more members.

SEC. 3. Any operator desirous of forming a Council shall, in conjunction with two operators of good standing, address a letter to any member of the nearest Council, to be by him presented to the Councillor; said letter to contain all necessary information regarding the number of offices which should be included in the new Council, also the names and positions of such operators as would probably become members of the Association within the jurisdiction of the new Council.

SEC. 4. If, in the judgment of the Councillor to whom application is thus made, there is sufficient evidence that the proposed Council can secure the required number of members and maintain sufficient strength to protect them from aggression, he shall appoint a suitable member of the Council over which he presides as an Initiating Officer, who shall be clothed with the necessary authority to initiate members, and shall be sent to the proposed headquarters of the new Council at such time as the applicants may appoint for their initiation.

SEC. 5. All necessary expenses of the said Initiating Officer shall be borne by the newly formed Council.

SEC. 6. When said Council shall number five or more members it may form a temporary organization, which shall continue until nine members have been initiated.

SEC. 7. Upon the acquisition of nine members the Councillor *pro tem.* shall apply to the Supreme Councillor for the designating number of the new Council; after receiving which, the Council may proceed to the election of permanent officers.

SEC. 8. In case the temporary Council shall not succeed in securing nine members, those who have already been initiated shall, at the expiration of one month, dating from the first initiation, be apportioned to the nearest established Council, until such time as the requisite number of members for the organization of the said new Council shall be obtained.

The Government of Councils.

ARTICLE VI.

SECTION 1. The officers of a Council shall consist of a Councillor, a Vice-Councillor and a Secretary.

SEC. 2. Any member of a Council in good standing shall be eligible to those offices.

ARTICLE VII.

SECTION 1. The officers shall be elected by ballot, and shall hold their respective offices until the fifteenth day of January next ensuing after their election.

SEC. 2. The election of officers shall take place on the fifteenth day of December of each year, and they shall enter upon the duties of their offices on the fifteenth day of January following.

SEC. 3. If, on the first balloting for any of the above offices, there shall not be a majority of all the votes taken in favor of one candidate, the members shall, upon the next balloting, confine their choice to the three candidates having the largest number of votes; and, after the second ballot, to the two candidates having the highest number.

SEC. 4. A majority vote shall be necessary for a choice.

SEC. 5. Any officer may at any time resign the duties of his office, by presenting a written resignation, which shall be read by the Secretary at a regular meeting of the Council.

SEC. 6. Should any office be left vacant by resignation or death, such vacancy shall be filled by the election of some member to serve for the remainder of the term.

ARTICLE VIII.

SECTION 1. It shall be the duty of the Councillor to attend and preside over all meetings of the Council, to represent at all times the interests of the members of the Council over which he presides in all cases of aggression by their employers, and, if necessary, tender for their protection the support of the Association: *Provided*, Such action be approved by a two-thirds vote of a meeting called for that purpose. He shall have power to suspend any member of the Council over which he presides, subject to the consideration and final action of the next ensuing meeting; also to call a special meeting of the Council, by giving five days' notice; to appoint

Digitized by Google

such committees as may be necessary to facilitate the transaction of business, and at each meeting of the Council to appoint a Guard, whose duty it shall be to prevent the ingress of improper persons.

SEC. 2. It shall be the duty of the Vice-Councillor to attend all meetings of the Council, and, in the absence of the Councillor, to assume all duties incumbent on that officer. He shall conduct the balloting for new members, and administer to them the obligation.

SEC. 3. It shall be the duty of the Secretary to attend all meetings of the Council and keep a suitable record of the proceedings, and to keep a complete register of the names of members, their ages, the date of their admission to the Association, and the name of one member by whom they were proposed. He shall conduct all correspondence pertaining to the business of the Council, and shall be entrusted with the finances of the Council, and shall levy such assessments upon the members as may be necessary to defray the ordinary expenses of the Council, and collect the same, and shall also make immediate returns to the Supreme Secretary whenever requisition shall be made upon the Council for funds. He shall keep an accurate and detailed account of all receipts and expenditures, and submit an annual report of the same for the approval of the Council. He shall also submit a quarterly report of the numerical strength of the Council to the Supreme Councillor, and notify him of all changes among the officers and members.

SEC. 4. In case any member shall neglect to pay an authorized tax, after being called upon twice, it shall be the duty of the Secretary to notify the Councillor of the fact, stating, if possible, the reasons for such default.

ARTICLE IX.

SECTION 1. It shall be the duty of every member of the Association to cheerfully acquiesce in all measures that may be duly initiated by the Council to which he belongs, in accordance with the letter and spirit of the Constitution. *The firm and unswerving loyalty of every member is the fountain of power, which must be maintained at all hazards.*

SEC. 2. Any member feeling that he has just reasons to complain of the action of any Company or member, will be expected to make a written statement of his case to the Councillor of the Council to which he belongs, and may insist upon a hearing.

SEC. 3. It shall be the duty of every member of the Association to conduct himself, at all times and in all places, in a manner becoming the character of the organization; and, while protecting him from aggression, *the Association expects every member to perform his whole duty toward his employers, in accordance with the terms under which he was engaged*, provided he does not thereby conflict with a duly authorized order from the Councillor of the Council to which he belongs.

SEC. 4. In case any member resigns a position, his duty shall be to notify the Councillor, giving his reasons for such resignation.

SEC. 5. No member shall propose a candidate for membership unless he be thoroughly conversant with his qualifications and habits, and fully satisfied that he will become a worthy and upright member.

SEC. 6. *Habitual* intoxication cannot be permitted, and inability to perform his duties by reason of such indulgence shall be sufficient cause for the suspension of any member.

SEC. 7. Every member is expected to notify all trustworthy operators of the existance of the Association, and acquaint them with its objects and purposes; but he shall urge no person to join it beyond assuring him of the high character of the organization.

Conditions of Membership.

ARTICLE X.

SECTION 1. Any telegraph operator of good standing, not under eighteen years of age, and who has resided within the jurisdiction of the Council to which he applies for admission, for one month, shall be eligible to membership in the Association.

SEC. 2. A proposition for membership must be indorsed by three members in good standing, and accompanied by an initiation fee of one dollar, and may be presented at any meeting of the Council, to be balloted for at the next ensuing meeting.

SEC. 3. The casting of three black balls shall be necessary to reject a candidate; and, in case of such rejection, three months shall elapse before his name can again be presented.

SEC. 4. After being duly elected, every candidate shall be required to bind himself by the following obligation, which may be administered by any officer of the Council, in the presence of two or more members. He shall then be required to subscribe thereto, which shall be placed on file by the Secretary.

Form of Pledge.

I, A—— B——, do hereby acknowledge that, having voluntarily become a member of the Telegraphers' Association, and being made cognizant with its objects and intentions, I do hereby pledge my sacred honor that I will aid, in whatsoever manner I may be required, the advancement and protection of its members, and that I will reveal neither the names of the officers nor members, nor the purposes of the Association, excepting so far as may be necessary to encourage the admission of new members; and I will obey all such rules or orders as may be promulgated through the proper officers, and sanctioned by a vote of the Council of which I am a member.

(Signed) A—— B——.

(Witness) C—— D——.

SEC. 5. Every member of the Association shall be entitled to a card of membership, to be signed by the Councillor and Secretary of the Council to which he belongs, and endorsed upon the back with the signature of the rightful owner, and cards to be renewed every six months.

SEC. 6. A card of membership shall be of the following form:

This is to certify that A—— B—— is a member in good standing of Council No. —, Telegraphers' Association.

——. ——, Councillor.

(Date.) —— ——, Secretary.

Good for six months from date.

SEC. 7. A card of membership, together with the password, shall entitle their rightful owner to admission to the meetings of any Council, and to recognition by any member of the Association.

SEC. 8. Any member may withdraw from the Council with which he is connected with the consent of a two-thirds vote of any meeting, and shall be entitled to a certificate of withdrawal, signed by the Councillor, which shall entitle him to membership in any Council without the payment of the usual initiation fee.

ARTICLE XI.

SECTION 1. Each Council shall have power to adopt such measures as may be necessary to guarantee to all of its members just treatment in accordance with their standing as members of the Association, and ample protection from all acts of aggression which may be imposed upon them.

SEC. 2. Each Council shall have power to adopt such By-Laws for the government of its members as it may deem requisite, provided no such laws in any way conflict with the provisions of this Constitution.

SEC. 3. No movement for the protection or advancement of the interests of any member shall be inaugurated, excepting it be authorized by a two-thirds vote of a meeting of the Council, five days previous notice having been given of the nature of the business about being acted upon.

SEC. 4. In the event of any such movement being authorized, it shall be the duty of the Councillor of the Council so acting to communicate in cypher by telegraph and mail with the Supreme Councillor and the Councillors of all other Councils, detailing the nature of the movement to be inaugurated, and invoking their aid in case it should be found necessary to call upon them for assistance.

SEC. 5. The Councillor of any Council receiving such notice shall immediately call a special meeting to take action upon it, and a two-thirds vote of such meeting in favor of the aforesaid movement shall be binding upon all members of the Council.

SEC. 6. Any member found guilty of a violation of the Constitution, or of his duties to the Association, may be expelled therefrom by a two-thirds vote of the Council to which he belongs.

SEC. 7. A majority vote shall be binding upon a Council in all cases, unless otherwise provided in this Constitution.

SEC. 8. Whenever action shall be taken by any Council bearing upon the general interests of the Association, a copy of the resolutions adopted shall be forwarded to the Councillor of each Council; and, should the nature of the business require it, he shall notify the Supreme Councillor of the action taken upon it by the Council over which he presides.

SEC. 9. This Constitution may be amended by a vote of two-thirds of the whole number of Councils.

SEC. 10. This Constitution shall take effect on and after the fifteenth day of January, 1872.

ECONOMIC ELECTRIC PILE.—M. Gaiffe has recently introduced to notice a new electric pile, devised by him with a special view to its universal cheap production. It resembles in form Callaud's cell, which has been employed for some years on telegraph lines but the elements are different. The poles are rods of lead and zinc, immersed in a 10 per cent. aqueous solution of ammoniacal chlorhydrate, contained in a suitable vessel. The zinc rod is only half the whole depth, whereas the lead rod reaches to the bottom, where there is a layer of saline oxide of lead (minium). The electro-motive power of this pile is about one-third of that of a Bunsen couple; its internal resistance is small and little variable, as the chloride of zinc formed does not sensibly change the conductibility of the exciting fluid; its constancy is great; and finally the cost is merely nominal, when the circuit is open.

M. MORIN'S ELECTRIC PILE.—This has been designed by the inventor to obviate the inconvenience resulting from the deposit of zinc, on the copper or on the porous vessel, that takes place in the ordinary sulphate of copper pile. A zinc cylinder is placed concentrically within a copper cylinder, and the latter is surrounded by a cylinder of filter-paper, replacing the porous cell. Between the copper and the paper is placed some rather hard sandstone, and flour of sulphur between the copper and the zinc. The element is immersed in a solution of sulphate of zinc, which penetrates the mass through minute perforations in the copper. Elements thus prepared have been in effective use during twenty months without supervision or attention, and are said to be capable of serving for as long again.

THE manufacture of the new submarine telegraph cable for the existing lines, is progressing rapidly. It is to be laid by the steamship Great Eastern during the Summer of 1873. The route will be from Land's End, in England, to Halifax, Nova Scotia, and thence by cable direct to New York.

FOREIGN TELEGRAPHIC ITEMS

SUBMARINE TELEGRAPH.—A dividend has been declared for the half-year at the rate of 15 per cent. per annum. The securities belonging to the company in the joint reserve fund, amounting to £31,693, have been transferred into the names of the trustees of the undertaking, and the proportion of reserve fund belonging to the "Société Carmichael et Cie," has been transferred into the names of their gérants.

MEDITERRANEAN EXTENSION TELEGRAPH.—The usual half-yearly dividend has been declared on the 8 per cent. preference stock, less income-tax, and a dividend at the rate of 3 per cent. per annum on the ordinary share capital, free of income-tax.

POST OFFICE TELEGRAPHS.—The total number of messages forwarded from Postal Telegraph Stations in the United Kingdom during the week ending August 17th, 1872, was 329,478, and during the corresponding week of 1871, 260,504, showing an increase in the week of 1872, on that of 1871, of 68,974, messages.

AN Act has been printed and passed at the close of the last session (35 and 36 Vic., Cap. 83) to extend the provisions of the Pensions Commutation Act, 1871, to officers and clerks of Telegraph Companies who are entitled to annuities. The statute is to apply to the officers of companies whose undertakings have been purchased by the Postmaster General

AN official communication from the Administration of the Russian Telegraphs gives notice that the twelve versts of telegraph wires recently destroyed by the inundations between Ustkara and Gorlitza, on the route to China, have been provisionally repaired; but that the telegraphic correspondence beyond Gorlitza will continue for the present to be forwarded by steamers, because further up, in the direction of Anikino, the line could not yet be repaired, as the country is still under water.

COURTING BY TELEGRAPH.

The report of Mr. Scudamore, the Director of Postal Telegraphs in Great Britain, is not exactly a novel, and yet it contains a romance of the newest and most original description. After saying how successful he has found the system of employing male and female clerks together, and how much the tone of the men has been raised by the association, and how well the women perform the checking or fault-finding branches of the work, he goes on to speak of friendships formed between clerks at either end of a telegraph wire. They begin by chatting in the intervals of their work, and very soon become fast friends. "It is a fact," continues Mr. Scudamore, "that a telegraph clerk in London, who was engaged on a wire to Berlin, formed an acquaintance with, and an attachment for"—mark the official style of the language—"a female clerk who worked on the same wire in Berlin, that he made a proposal of marriage to her, and that she accepted him without having seen him. They were married, and the marriage resulting from the electric affinities is supposed to have turned out as well as those in which the senses are more apparently concerned." Nor must the prudent reader run away with the idea that these young persons were very rash, or that they married without due acquaintance. For it is a fact that a clerk at one end of a wire can readily tell, by the way in which the clerk at the other end does his work, "whether he is passionate or sulky, cheerful or dull, sanguine or phlegmatic, ill-natured or good-natured."

COMPARATIVE TESTS OF INSULATORS.

Date.	Time.			Resistance per Insulat'r		Humidity.	Temperature.	Remarks.
				Glass.	Pond.			
1872.				Meg-ohms.	Meg-ohms.			
July 25.	11	15	a.m.	189	210	94°	70°	Raining about 10 minutes.
"	12	05	p.m.	136	290	"	"	Raining
"	2	55	p.m.	80	140	"	"	Very hard rain 10 minutes.
July 29.	12	00	m.	72	400	70	80	Hard rain 10 min.
"	12	30	p.m.	100	250	"	"	Drizzling.
Aug. 28.	2	00	p.m.	640	1840	95	69	Commenced mist
"	4	30	p.m.	24	1100	"	"	Heavy mist.
Sep. 11.	12	17	p.m.	7	60			

The Glass Insulators used in all these tests are the same. They have been exposed constantly since July 20.

The Pond Insulators of July 25 and 29, were exposed at same date with the glass, while those in test of Aug. 28 are of the improved form now adopted by the manufacturers, and had been, at the date of this test, exposed but about 12 hours, and probably show a higher test from their cleanliness. They were carefully wiped before being put on the frame. Otherwise the conditions of exposure are precisely alike.

These tests are only valuable as giving comparative figures, and not absolute units of resistance.

The tests of September 11th were made during a heavy rain, which had continued constantly for nearly two days. The Glass and Pond Insulators were put up at the same time.

Lines insulated with glass were working very hard, while those of the same length insulated with the Pond Insulator worked well.

LIABILITY OF TELEGRAPH COMPANIES.

An important legal decision was announced at the last term of the law court in this district, which settles the law in this State as to the liability of telegraph companies to their employers in case of failure to transmit or deliver messages. As the case (George W. True *et als.* against International Telegraph Company) is of novel impression in our courts and of interest to the public, we give a brief statement of facts. In 1870, George W. True & Co, of this city, sent a dispatch to their correspondents in Baltimore, accepting an offer of a cargo of corn at a given price and freight. The offer had been made by telegraph the same day, and the reply was sent on a "night blank" of the International Telegraph line at the usual night rates. The dispatch, on account of the carelessness of some operator on the line west of Boston, was not duly forwarded, and True & Co. failed to secure the cargo of corn. As the market price of corn and freights advanced immediately, they were obliged to buy other corn to meet the wants of their business at a price largely in advance of that offered. A claim was immediately preferred against the telegraph company for the damage resulting from their failure to promptly transmit the message to its destination, which was resisted by the company on the ground that one of the conditions printed on their "night blanks," subject to which the message was sent, was that the telegraph company should not be liable, in case of failure to deliver the message, to an amount greater than the sum paid for its transmission —in this case, forty-eight cents. Suit was therefore brought to recover special damages; the case was argued July, 1870, and has been under consideration two years; the court has now rendered a decision in which the claim of the plaintiffs is sustained in full.

The ground of the decision was that, although telegraph companies may establish reasonable rules for the conduct of their business, they cannot by printed notices on their blanks relieve themselves from the liability which the law imposes on them from motives of public policy; that the courts are to determine in the last resort whether the rules and limitations prescribed by the company are reasonable, and that the condition set up in defense in this was not binding upon the plaintiffs, as it attempted to relieve the telegraph company from all liability (beyond the amount paid for the message), whether arising from carelessness, accident or wilful default of the company and its servants. The measure of damage was declared to be the difference between the price of the cargo offered and of that bought to supply its place, with the additional freight.—*Portland (Me) Press.*

RECEIPTING FOR TELEGRAMS.

At the meeting of the Board of Trade last Saturday night the following resolution was adopted:

Resolved, That the delegates of this Board to the National Board of Trade be instructed to use all proper efforts to have such action taken at the ensuing session of the National Board as may, in the opinion of the members thereof, be necessary to influence the various telegraph companies of this country to receipt to the senders of telegrams for messages sent and money paid therefor, and to require the different companies to distribute and publicly post their private tariff rate at their various offices.—*Cincinnati Times.*

TO RENDER METALS ELECTRIC.—T. Sidot has observed this phenomenon, and found that iron, silver, and aluminium, if the friction be sufficient, will give off electric sparks. To perform this experiment, take a perfectly dry tube of thick white glass and put in 15 to 20 grammes granulated silver, and 30 to 40 grammes pure bisulphide of carbon, and seal up the tube. On warming the tube slightly and shaking it in the dark, sparks appear in the interior, their number increasing with the violence of the agitation. The sparks disappear on immersing the tube in water.

M. BOUMAN, of Holland, has effected a considerable improvement in the arrangement of the Leclanche battery, which renders it still more constant. It consists of a plate of carbon and an amalgamated zinc rod covered with woollen cloth, placed vertically in a glass jar, which is two-thirds filled with the mixture employed for this description of battery, namely, coarsely powdered carbon and peroxide of manganese. The contact with the carbon is made by cutting a slit in the carbon, and inserting a platinum wire, which, it is stated, establishes a good connection. Excellent results are stated to have obtained from this variation.

AN instrument has been invented in Germany which will measure with perfect accuracy the heat of the hottest furnace. It is based on the principle that the resistance of pure metals to the electric current increases with the temperature in a very simple ratio. A platinum wire of known resistance is coiled around a cylinder of fine clay, and covered with a tube of the same material. The test is a Daniells battery of two cells, and with a resistance measurer, and placed in the furnace whose temperature is to be ascertained. It is then only necessary to read off the indications of temperature on the graduated resistance measure.

CORRESPONDENCE.

LETTER FROM MR. J. D. REID.

Observations upon the Telegraph Systems in Europe.

EDINBURGH, Aug. 20, 1872.

To the Editor of the Journal of the Telegraph.

I said nothing of telegraphs in my last, because my journey has been largely an escape from them. The telegraph to me is the memory of twenty-seven years of toil, which have not passed without leaving their marks upon me. These I have been rubbing out, and with much success. I have gained flesh and vigor, and approach new duties with gayety and youth.

The telegraph lines in the north of Switzerland disappointed me. They looked like the earliest American telegraphs: slim poles, an iron rim round the top (which, by the way, I was the first to use, and the utility of which I now question), and a glass insulator of the old ink-horn fashion, on an iron pin. The wire was small and unzinced. Yet the poles were all very straight, and in good order. The iron pole is quite a feature, and is neat and serviceable. They are simple rods, averaging from ten to twenty feet long, seldom the latter, and bear from three to ten wires. I see not why, with a good foundation of a single square stone or block of black locust, they could not be economically introduced on some American roads. In lower Switzerland, the new lines show evident care and regard for permanence. The poles are larger, all very straight, and wherever the least curve occurs a second pole is planted in rear of the wire-bearer, and is made to lean against and keep it straight by securely bolting thereto. This is done at every deviation from a straight line. A new insulator is used there made of porcelain, having the iron shank depending on which the wire rests, and so formed that they have two lugs through which spikes pass, which fasten them to the poles. The hook is a simple wire, on which the line-wire rests without fastening, which is only done about every ten poles, on an insulator borne by a bracket. The new wires are all coated and somewhat larger, although I think only for international wires.

On my way through the country I had sometimes occasion to telegraph, and was always pleased with the neatness of the stations and the civility of the attendants. Some of the stations are at the smallest places, evidently for the accommodation of occasional travellers or for line police. In every case the machinery was carefully excluded from sight, and approach to it guarded. Almost all the operators I met were young women, who fortunately understood my mangled French, but were ignorant of English. I enclose you one or two specimens of messages I received from Strasbourg and Zurich, at which latter place I had the ill fortune to be robbed while bathing in the lake, at the close of an intensely hot day. My answers were usually received promptly, and I have no question of the efficiency of the general service. The chief officer at Bern is a most careful and obliging person. I noticed nothing remarkable in the detail of duty, except a prevailing cleanliness and courtesy which might have been instinctive, or the reflection of authority, or both. These are cheap but most attractive appendages to any office, and which our American offices are more and more attaining.

Throughout France, Belgium, and Germany, as well as through Great Britain, the lines are all carefully built, and sometimes the poles bear an enormous multitude of wires. The insulators on the continent are almost universally of porcelain, of large size, to which the wires are bound, except where the new lugged insulator is used. In England and Scotland the insulators are largely of vitrified earthenware, but of the same form as the porcelain. In Great Britain every pole is guyed by iron cords, to preserve it from falling or losing its upright position. I was surprised to find the covered wires which pass through the long underground railroads of London simply hung loosely and all together on a single nail driven into the wall. Sometimes a dozen are thus suspended. I cut the following from a morning paper, which may serve as an item for you:—

"FIGURES IN TELEGRAMS.—A new rule in regard to figures in telegraphic messages came into operation on the 1st inst., to which it is desirable the attention of the public, and especially of business men, should be directed. The transmission of figures by telegraph has always been a difficulty. Despite the regulation of the postal department that '365' should be held as written thus: 'Three hundred and sixty-five,' and counted as five words, the public cannot be got to write the figures in words at length. The new rules are in general such that the sender of a message will gain by directing his figures to be sent in words. Thus, the word 'first,' when written so, must, according to the rule that any word in Johnson's Dictionary is to be accepted as one word, be charged single. But if the sender of a telegram writes it '1st,' this is to be counted as two words. In the same way '13th' is to be counted as three, because in that form the telegraph clerks must send it 'one, three, th.' But the sender can write 'thirteenth,' and in this way, we assume, it must pass as one word. In the same spirit the new rule affects fractions, for while 'three-fourths,' when so written, are unmistakably chargeable as two words, the regulation counts it as three when written '¾,' the bar of division in this form requiring a special signal. Again, '12.35' (as applied to a train) will be charged five words in that form, but if written 'twelve thirty-five,' only as three. In the form of words, the meaning can generally be as accurately conveyed, and as there is an actual saving in the adoption of that form, we have no doubt the new regulations adopted by the post-office will have the effect of reducing the use of figures and fractions in telegraph messages."

I observe a new regulation also, which, whatever it does not do, certainly saves time, and either increases the messengers' gains or reduces the cost of service. Where I sit the business is largely done by telegraph, and requires great promptness. The department has, at its own expense, and without request, procured printed envelopes bearing the firm's address, and messages are delivered *without receipts*. The boys rush in with a message, slap it on the counter, and are off. I intend to inquire about this, and write you about it after I return.

Yours truly, J. D. REID.

To the Editor of the Journal of the Telegraph:

I desire to avail myself of the medium of your paper to lay before the members of the Telegraphers' Insurance Association a proposition which, it seems to me, would, if adopted, tend greatly to the benefit of that institution. It is that its headquarters be removed to some western city.

It is a fact that an undue proportion of membership is at present contained in and about New York. Telegraphers throughout the west and south manifest comparatively little interest in the affairs of the Association. This, I believe, is due more to their being so far removed from the headquarters of the Association than to any other cause. Sectional feelings may possibly also have an effect. At all events it cannot be doubted that the selection of well known telegraphers resident at some central point in the west, as officers of the Association, would tend to awaken an interest where it has not previously existed.

But a short time intervenes between this and our next annual meeting, but it is sufficient for a full consideration of the subject and the forming of a wise decision. To this end it would be desirable that such of the members as feel enough interest in the subject, should express their views through the columns of the JOURNAL.

A NEW YORK MEMBER.

AUSTIN, Texas, August 7, 1872.

To the Editor of the Journal of the Telegraph:

A question arose to-day as regards the correct way of counting N. O. or N. Y. Party who brought message to office read it to the receiver, explaining the fact that N. O. meant New Orleans. The message read: "Let me know what you heard from N. O., &c. I don't feel like going there," evidently meaning a place. I referred to page 10 of the Rules, claiming it one word. No delay occurred but merely the question of the correct method of counting N. O., receiving operator claiming that receiver has no right to know whether N. O. meant New Orleans, not even though it was so explained by sender. Please answer.

OPERATOR.

Answer.—A rule cannot be framed which will cover every case which might arise, and with which it appears to be connected. At such times common sense comes into play, of course keeping in harmony with the spirit of the order. In this case, as the abbreviation of N. O. for New Orleans was understood by the receiver, it was correct to count it as one word. In another connection it might have been right to have counted it as two words. The operator receiving the message, however, had no right to dispute the accuracy of the check after having been informed by the sending operator of the manner in which it was counted. Authority is frequently assumed by receiving operators in cases of this character to refuse business unless their peculiar ideas of right is conformed to, and thereby delay to business is sometimes occasioned. This is wrong; and in this connection we quote, for general information, the rule which governs service of this nature:

"Rule 20. In order to prevent delay in the transmission of messages, arising from differences of opinion as to their proper route or mode of counting, the sending office will select the wire over which its business shall be sent, and decide as to the number of words contained in the names of places and things or in compound words.

"No office shall refuse to receive and forward or deliver any message from any other office, unless it should endanger life or property, in which case the receiving office will hold such message until advised by the District Superintendent.

"If any message is improperly sent or counted, the Manager of the receiving office will immediately notify the District Superintendent."

HARTFORD CITY, Ind., Sept. 9, 1872.

To the Editor of the Journal of the Telegraph:

Please tell me through the columns of the JOURNAL, how many words in the following message:

"Will pay thirty-four on track for your wheat. Answer. Detroit. R. M. SMITH.
For JAS. B. JONES."

All of the above signature was transmitted.

Answer.—There are fifteen words. The four words after the signature R. M. Smith, should be counted.

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory and Province on the Continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JOURNAL OF THE TELEGRAPH,

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, SEPTEMBER 16, 1872.

EVIDENCES OF INTEREST TAKEN IN THE JOURNAL.

It is exceedingly gratifying to observe the great interest which is springing up among the operators in all parts of the country in all matters relating to practical telegraphy, and especially to note the interest which they manifest in the Journal. We have aimed to present in every issue of the paper useful and instructive articles relating to the most important branches of the service which should be the means of assisting those who have a desire to learn to reach positions where their services would be of more value to the Company and of profit to themselves. We have believed that the telegraphic field was not only broad, but that it contained a rich and fruitful soil; and if good seed was sown upon it, it would yield a good and abundant harvest. This harvest has begun sooner than we anticipated, and promises to be much more abundant than we could have hoped. Every day we are in receipt of communications relating to the science or business of telegraphing, from operators in all parts of the country, testifying to the great interest which they take in our efforts to instruct and benefit them. These evidences of appreciation are very acceptable, and we are very glad to receive them. It is evident that the good will and interest so freely tendered to the employés of the Company by the possession of an able journal devoted to their service is being not only appreciated, but that there is a desire to reciprocate by a service in kind, which is manifested by the numerous valuable communications made to the Journal.

Quite recently we have had occasion, in answering correspondents, to decide certain questions which arose in the ordinary course of business, and which seemed to be not generally understood. Some of these decisions have been misapprehended, and it has been gratifying to us to receive communications from those who supposed we were wrong, setting us right. Our thanks are due to these vigilant guardians of the reputation of the Journal.

Had we space we would publish every letter; but as this is not practicable, we must be content to refer to them. Our esteemed correspondent, Savannah, is mistaken in supposing we counted "half past" one word and P. M. two words in the following message: "Your sister-in-law died at half past five this P. M. Answer." He is quite correct in saying that sister-in-law is properly counted as one word, its legitimacy being established by the best authorities, and that half past is not one word, any more than is quarter past or three quarters past, none of which are recognized by Webster. The hyphen between the words half and past was a typographical error. We think Savannah is correct in saying that etc. should be counted as one word on the ground of usage. Our guide in the matter of counting is the book of rules and Webster's Dictionary. Any word found in the latter is to be transmitted as one word.

Our reply to the question in the Journal of any 15th, whether the sender of a red message can have it repeated back upon the payment of one half of the amount of tolls charged for sending the message, must be changed from the affirmative to the negative. In the conditions for repeating back, as printed on blank No. 2, it is provided that for repeating, one half the regular rate is charged in addition; but the rate charged on red messages is not the regular rate, but one half the regular rate, and it would be manifestly improper to assume the responsibility of a repetition of the red message for one quarter the regular tolls. The Company assumes no responsibility for red messages, and cannot, therefore, repeat them back nor insure them.

If a party sending a red message desires the signal 34 to accompany it, he must pay one half the usual day rate for this extra service—that is to say, one full day rate for the red message and the answer. The receiving office should return the answer just as soon as the message has been delivered to the party addressed.

No United States official, whether attached to the Post-office or any other branch of the public service, has any right to send messages free over the wires of this Company unless he possesses a duly authorized pass or frank. Hampton should have referred the matter at once to his Superintendent. The operator who received the message from the Post-office clerk showed a great lack of knowledge and discretion in receiving it as a free message on the assertion of the Postal railway clerk that it was entitled to go free. Whenever the government business is to be sent free over the Western Union lines there will be due notice from the officers of the Company, and until this is issued the assertions of Postal railway clerks that their messages are to be sent free may be safely disregarded.

Whenever any operator is known to make improper use, by his superior or other person, of any information contained in a message received at or transmitted from his office, he will be derelict in his duty, and really accessory to the dishonest use of the information, if he does not promptly notify his Superintendent of the fact. Such use of information is just as wrong as the appropriation of property which does not belong to you, and should be reported as quickly as that of a theft.

It will be seen by referring to the accompanying executive order that the restriction upon the delivery of red messages until the day following their transmission is removed, and that such messages, when called for by the persons to whom they are addressed, may be delivered to them the same night upon payment of the difference in rates. The Company does not agree to send them until night or the next morning, and does not agree to deliver them until the next day, but in cases where the business is such that they can be sent the same night, and parties come to the office for them, they may be delivered to them.

An operator should never send red messages over any circuit before all regular full-rate messages belonging to such circuit have been transmitted. Full-rate messages must always be got off before the half-rate business is sent.

In another column we print a communication from a prominent member of the Telegraphers' Life Insurance Association, suggesting the removal of the headquarters of the Association to some central point in the West. The conclusions which prompt this suggestion have been arrived at after much deliberation among the more active members in this section, and are believed to be essential to the growth and continued prosperity of the Association.

We can say but little to add force to the ideas expressed by our correspondent, and that must, for obvious reasons, coincide entirely with his views. It appears very strange to us, and, doubtless, to our readers also, that, with at least ten thousand persons directly connected with our business, less than one-tenth belong to the Association and are in good standing, while of that number the greater proportion are in the immediate vicinity of its headquarters. Has sectional jealousy anything to do with this? We hope and believe not; but still the experiment of removal had better be tried.

The sentiment of charity upon which the institution was founded, long since passed away. Membership now is a matter of business. At this day it has become a recognized duty that a man should make provision for those dependent upon him, in the event of his being taken away. To say nothing of the pleasant feeling of brotherhood engendered by the Association, and the manifest favor and interest taken in its welfare by the officers of the Western Union Company, the fact is plain that this system of life insurance is the cheapest, and the form of assessment the least objectionable, of any that could be devised.

No one has an ax to grind in this institution. No one receives any of the funds except those who, by misfortune, become entitled to them.

In this view, the paucity of members is incomprehensible to us. There should be a membership of at least five thousand, to make it a real benefit and success; and it is in the hope of attaining these proportions that we advocate the suggestions which give rise to these remarks.

Let us have the views of each member of the Association. We will publish all that we can find room for.

OBITUARY.

JOHN HORNER.

Mr. John Horner, Cashier of the New York Office of the Western Union Telegraph Company, died at the Gilsey House in this city, on Tuesday, September 10. This event, with the record of his life, deserves something more than a passing notice.

Mr. Horner had been suffering for many months from a painful disease, which entirely incapacitated him from the active duties of his position, but from which he was believed to be recovering, until about the middle of the past Summer, when he had a relapse. Pneumonia developed itself, which was the immediate cause of his death.

Mr. Horner was preeminently a self-made man. The success of his life was due to his inherent qualifications for the business in which he was engaged, together with his indomitable energy, and must serve as a bright lesson to those who are now filling positions similar to that in which he first embarked, a very young man, in 1846, in the very infancy of the telegraphic business.

In that year he entered the service as receiving clerk for the Magnetic Telegraph Company at Philadelphia, and remained there until 1850, when we find him in New York as Cashier and Receiver for the New York and Philadelphia, better known as the "House" line, which had its headquarters and only office at No. 21 Wall street. With this Company and its successors he remained until his death, every change bringing promotion to him, until, in 1866, upon the consolidation of all the existing Companies, he was appointed Cashier of the New York Office, a position in importance equalled by few in the telegraphic service.

Those who have had business at the General Office, No. 145 Broadway, will remember Mr. Horner's genial and pleasant face, as he was always at his post while in the enjoyment of health. He always had a pleasant word and smile for every one, and many a wrathful customer, who had charged upon him lion-like, retired as gentle as a lamb, soothed, if not satisfied. Those who are familiar with the tribulations of a telegraph receiver can best appreciate this talent and command of temper.

Mr. Horner was a shrewd business man, and those who did not well know him were apt to regard him as being a hard and difficult man to deal with. The writer, who was a very diminutive, tow-headed urchin in 1851, the only messenger employed by the "House" line, and who was under his immediate authority, knew him well, and knew of his many generous actions, to others as well as to himself. His generosity was limited only by his ability to gratify it.

He had his faults, as, indeed, who of us has not; but they were not glaring, and were more than atoned for by his many virtues.

Thus, one by one, those who have been identified with the telegraph from almost its inception in a practical form, are passing away. May he rest in peace.

In another part of the JOURNAL we present to our readers the preamble and rather lengthy constitution of an organization calling itself the "Telegraphers' Association." We give it the benefit of our circulation, out of pure kindness and to inculcate a lesson. In a future number we shall probably have something to say upon the subject. Meanwhile, digest it thoroughly.

We cannot inform our correspondent at Bedford, Iowa, where operators' badge or key pins can be procured.

WESTERN UNION TELEGRAPH COMPANY,
TREASURER'S OFFICE.
NEW YORK, September 16, 1872.

Executive Order, No. 141.

1. Messages to be transmitted at half rates will hereafter be received at any hour during the day until offices close for the night. Offices open all night will receive such messages until midnight.

2. The tolls on half-rate messages will in no case be less than twenty-five cents.

3. If a half-rate message has been received at the place of destination, and the party to whom the same is addressed calls at the office for it, the message may be delivered to him on his paying the difference between half rates and full rates on such message. No change will be made in the time of delivery of half-rate messages not thus specially applied for.

Anything in Order No. 94 in conflict with the above is hereby abrogated.

WILLIAM ORTON, President.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, Sept. 9, 1872.

To Transfer Offices.

Section 7 of Instructions to Managers provides, that when the payee of a transfer order cannot be found within forty-eight hours, the Manager shall notify his local Transfer Agent of the fact, by telegraph, stating reasons, &c.

Managers are hereby instructed that after such notice to the Transfer Agent has been given, the order must be considered as cancelled, and no payment, in such case, can be made without a new order from the Transfer Agent.

G. H. MUMFORD, Vice-Pres't.

To Transfer Agents.

Referring to the above notice, and to Section 7 of Instructions to Transfer Agents:

If the payee of a transfer order does not call for the amount within forty-eight hours after proper efforts have been made to find him, the order should be cancelled and the receiving office directed to refund the same, retaining all tolls and premiums.

G. H. MUMFORD, Vice-Pres't.

STEARNS' DUPLEX INSTRUMENTS ON THE NEWFOUNDLAND LINES.

We learn from Mr. Henry H. Ward, Superintendent of the New York and Newfoundland Telegraph Company, who has just returned from a trip with Mr. Joseph B. Stearns, to introduce the duplex instruments on the lines of the company connecting with the Atlantic cables, that the instruments have proved a great success. The lines from Heart's Content to Plaister Cove, *via* Placentia, St. Pierre and Sydney, 554 miles in length—of which 332 miles are cable, in two sections, of 124 and 208 miles—work perfectly through the duplex, largely increasing the capacity of the lines for business.

Mr. Stearns is yet at Sydney, completing and perfecting the arrangements, but will return home in a few days.

The lines in Northern regions have heretofore been very much troubled and interrupted by aurora, which in those regions is much more frequent than in lower latitudes. During the experiments they found that, by disconnecting the wires from the earth and establishing a complete metallic circuit, all the effects of the auroral current were obviated, and the wires could be worked as perfectly as when there was no aurora visible. For lines in northern latitudes this is an important fact, and even where auroras are comparatively infrequent the demonstration will suggest a method by which the delays heretofore incident to auroral displays may be obviated.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
September 16, 1872.

To all Offices on W. U. Lines:

THE NEW TARIFF BOOK WILL GO INTO EFFECT OCTOBER FIRST, 1872.

Many of the offices have been directed by their superintendents that, with certain exceptions, the book might be used as soon as received. Such offices are hereby notified that the new book will be used on and after the above date, for rates, subject to the exceptions named hereafter in this order, to ALL points.

It is not intended that ANY *changes in present rates be made, except such as are given in* STATE RATES, RATES TO NEW SQUARES, 1 to 6 inclusive, 501 to 589 inclusive, AND RATES TO SQUARES 127 AND 128. If any increase in present rates to other points or squares is observed the present rate should be retained, and the increased rate reported to the Dist. Supt. The "LOCAL" and "SPECIAL RATES" *will remain unchanged.* The instructions in the book in regard to "local rates" are for new offices or for "local rates" not already determined. "Square rates" to all squares, except 109, 118, 127, 128, 149, 158, 168 and 190 (rates to 109, 118, 149, 158, 168 and 190 have been purposely omitted, there being no offices in these squares at present,) are the same as those given on tariff sheet now in use.

Lists of CHANGES IN NAMES AND RATES, ADDITIONAL NAMES, &c., will be found in the supplement of this number of the JOURNAL.

All CHANGES, &c., in the printed matter of the new book are given on the first half of the supplement. *These changes should be entered neatly and correctly* WITHIN TWENTY DAYS AFTER THE RECEIPT OF THE JOURNAL. The leaf upon which they are printed should then be folded, endorsed as follows:

(*Name of office,*)
(*Date of receipt,*)
(*Date of mailing,*)
(*Manager's name,*)

and mailed to your Western Union District Superintendent.

The ADDITIONAL NAMES of offices should be entered in the tariff book, but the page upon which they are printed should be preserved for future reference.

If the number of the square on your tariff sheet does not correspond to that before the name of the office in the alphabetical list in the book, report the fact immediately to your superintendent.

Managers are requested to report any inaccuracies or omissions they may observe in the new tariff book to the Tariff Bureau.

We are notified by the Cuba Cable Co. that their cable to Havana is still interrupted, and that on and after Sept. 18, 1872, an extra charge of three dollars, gold, should be added to the charge for each Cuba cable message to pay charges for dispatch boat between Key West and Havana.

WILLIAM ORTON, President.

Every office should exhibit a sign "Western Union Telegraph." The Supply Department is prepared to furnish the *Standard* sign—white letters on a blue ground. Fancy colors and shaded letters are prohibited.

NOTICE is hereby given, that Cyrus L. Negley, late a Foreman of Repairs in the Eighth District, E. D., is a defaulter, and has absconded. Any information that may be obtained relative to his whereabouts or his conduct should be communicated at once to D. H. Bates, Superintendent, Philadelphia.

ANNUAL MEETING OF THE GOLD AND STOCK TELEGRAPH COMPANY.

The annual meeting of the Gold and Stock Telegraph Company was held at the office of the Company, No. 61 Broadway, in this city, on Tuesday last, September 10, and the following gentlemen were elected Directors for the ensuing year: Tracy R. Edson, William Orton, Horace F. Clark, Joseph M. Cook, Marshall Lefferts, James H. Banker, Alonzo B. Cornell. At a subsequent meeting of the Directors, Marshall Lefferts was elected President; Joseph M. Cook, Vice-President, and Norman C. Miller, Secretary and Treasurer.

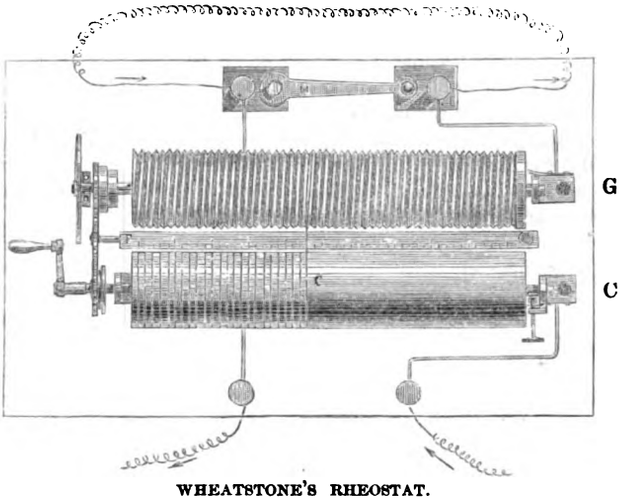
VOL. V. NO. 21. NEW YORK, OCTOBER 1, 1872. WHOLE NO. 118.

WHEATSTONE'S RHEOSTAT.

The rheostat invented by Mr. Wheatstone, is an instrument, by the aid of which, resistonces from the smallest to the largest, can be accurately measured.



This apparatus is composed of two cylinders, G C, the one metallic, the other wooden, or hardened caoutchouc, and of exactly the same diameter, and whereon a very fine German silver wire can be rolled and unrolled alternately; the latter's resistance being previously known. In order that the turns of the wire when rolled upon the wooden cylinder G may be well separated from each other, the cylinder is channeled in its full length by a fine helicoidal furrow, like a screw. An indicator placed at the extremity of the instrument at the end of these cylinders, or a graduated ruler, E F, enables us to count not only the number of turns of wire made by the cylinders, but even the fractions of turns. Finally, the apparatus is so constructed, that when we turn one of the cylinders, the other turns at the same time, so as to let the wire unroll on one side, as fast as it rolls up on the other. In order that the rheostat may be in good condition, the wire ought to be kept stretched out all the time, between the cylinders.

As a complement for this instrument, there is required:—firstly, a set of resistance-coils, gauged at the same unit as the wire of the rheostat; secondly, a sine or differential galvanometer. With these accessories the use of this apparatus is easy to understand.

Suppose, for example, we wish to ascertain by means of the differential galvanometer, the resistance of a piece of wire: the two extremities of this wire should be connected with the two poles of a battery, interposing on the thus formed circuit one of the wires of the differential galvanometer; from the same poles of the battery another circuit should be made, in which the wire of the rheostat, and the second wire of the differential galvanometer are interposed. Care must be taken to arrange the connections in such a way, that the two currents shall pass through the galvanometer in opposite directions.

When the rheostat is turned, so that all the German silver wire is rolled up on the copper cylinder, it offers no appreciable resistance, and the needle of the galvanometer will strongly deviate under the influence of the current which crosses the cylinder, because the second current is weakened by its passing across the resistance of the wire which is to be measured; but if the German silver wire is successively rolled up on the wooden cylinder, the first current is obliged to follow this wire in its different revolutions around the isolating cylinder, and there is a moment when the resistances of both circuits are precisely equal, one being weakened just as much as the other. Now, this moment is indicated when the needle of the galvanometer returns to zero. Then we stop the rheostat and read from the index the number of turns, and fractions of turns marked there, which indicate the unknown resistance.

The wire of the rheostats usually contain a resistance of about ten miles of No. 8 iron wire, or one hundred and fifty ohms, but when the resistances to be measured are greater than this, additional gauged coils are interposed into the circuit of the rheostat, and then the rheostat serves to make up the differences.

WHEATSTONE'S RHEOSTAT.

This method of measuring resistances is called "the differential method," but there is another to which the name of "method by substitution," is given, which has equal advantages, and which requires nothing but a simple sine or tangent galvanometer.

In using the latter method, the galvanometer is interposed in the circuit for measuring, and the deviation of the needle is noted down; we then substitute in place of this circuit, that of the rheostat; the resistance whereof is increased, until the deviation of the galvanometer coincides with the first reading.

This increase of resistance exactly indicates the resistance of the circuit measured. The inconvenience of this method is, that the variations in the strength of the battery may affect the indications upon the galvanometer.

In the perfected rheostats the wire pushes forth just before being unrolled, a currier's knife, which stops the cylinders the moment that the wire arrives at its starting point. By this means, the breaking of the wire is avoided. In order to secure a good connection between the rheostat wire and the outside circuit, the axles of the cylinders, to which both extremities of this wire are soldered, are provided with iron disks, which dip into little troughs, filled with mercury. In this way the connection is maintained through the mercury.

ELECTRO MAGNETS.

The electro-magnet performs so important a part in all systems of electric telegraphy that we deem it necessary to devote some space to the exposition of their properties and to the examination of the conditions of the developement of their magnetic power.

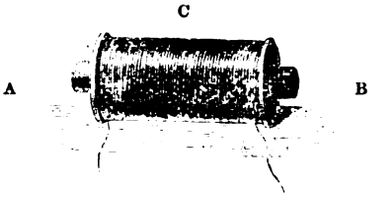


FIG. 1.

In the accompanying illustration (Figure 1) C is a bobbin, around which is rolled a long copper wire covered with silk, into the interior cavity of which is placed a bar of soft iron, A B. At the moment that an electric current is transmitted over the wire of bobbin C, the bar A B becomes a magnet, remains magnetic as long as the current continues to pass, and relapses into the neutral state the moment that the current is interrupted. Moreover, according to the theory of Ampere, the south pole of the magnetic bar is always at the left of the current, which traverses the wire of the bobbin.

The most common experience shows that the magnetism which is developed in the bar increases with the strength of the current. It is evident, besides, that, the strength of the current remaining the same, the magnetic power of the current is proportional to the number of convolutions of the conducting wire, provided the diameter of the bobbin be within such limits that the action of the current remains comparatively independent of the distance of the wire from the soft iron bar.

As the result of experimental research, Messrs. Lenz and Jacobi deduced the law that the magnetic force developed in a soft iron bar is proportional to the product of the strength of the current by the number of turns of wire which surrounds the core.

Mr. Muller has demonstrated, that this law is correct, as long as the operation is conducted with feeble currents on cylindrical bars, the diameter of which are not very small in proportion to their length. He has established besides, that between the limits within which the law of Messrs. Lenz and Jacobi stand good, the magnetic forces developed in the soft iron bars are proportional to the square roots of their diameters.

By indicating by m the developed magnetic intensity, by I the quantity of the current, by n the number of convolutions of the wire, by d the diameter of

Digitized by Google

the soft iron bar, and by c a constant quantity, we have consequently

$$m \quad cnI\sqrt{a}$$

But the experiments of Mr. Muller prove at the same time, that the proposition of Messrs. Lenz and Jacobi cannot be accepted as a general law. It appears, in fact, from his experiments, that for each soft iron bar, there is a *maximum* of magnetic intensity, which cannot be exceeded. This maximum is proportional to the diameter of the bar.

The electro-magnets, however, used in all systems of electric telegraphy are always operated under such conditions, that the law of Messrs. Lenz and Jacobi are applicable to them, and the magnetic intensity of the iron bar without any appreciable error can be reprepresented by the preceding formulæ.

While, on the one hand, the multiplication of the number of convolutions of wire on the bobbin increases the action of the current on the soft iron bar, on the other hand it diminishes the quantity of the current passing through the wire by making a considerable increase in the resistance of the circuit. Consequently there is a certain arrangement of the wire of the bobbin, which cannot be deviated from, that with a given battery, and acting in determined conditions, will communicate to a soft iron bar the *maximum* of magnetic intensity.

Between the limits in which the law of Messrs. Lenz and Jacobi is applicable, experience and the considerations deduced from the laws on voltaic currents agree in establishing the following rule:

When the resistance of the wire on the bobbin is equal to the resistance of the exterior circuit of the electro-magnet, including that of the battery, the *maximum* of magnetic intensity is obtained.

The electro-magnets, used in electric telegraphy, are made in the form of a horseshoe.

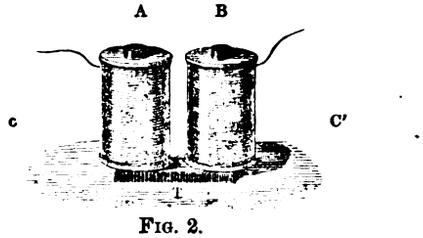

FIG. 2.

C C', figure 2, are the two bobbins, A B the two soft iron bars; T is a breech of soft iron, which connects the two bars. These electro-magnets are of two kinds, called relay magnets and register magnets, or sounder magnets.

The first are placed in the circuit of the main line, which extends between the two corresponding stations. In this case the resistance of the exterior circuit is always very large.

In order that the resistance of the relay may be equal to that of the remainder of the circuit, without its mass occupying too much space, the bobbins of these electro-magnets must be made of very fine wire, forming a very large number of convolutions around the bars. As the distance over which telegraphic circuits are worked vary according to circumstances, it is practically impossible that the electro-magnet placed in the circuit of the line can absolutely attain in every case the conditions of *maximum* intensity deduced from the law of Messrs. Lenz and Jacobi. Upon the lines in this country the resistance of the relays generally run from 125 to 150 ohms, although some are in use containing three or four times as much. In France the main line magnets generally have a resistance of about 2,000 ohms, the wire which is used being fine enough to contain about 2,000 turns, without making the magnets inconveniently large.

The electro-magnets of the second class are operated by the local batteries of the stations in which they are placed. In this case the exterior circuit is very short, and its resistance reduced nearly to that of the battery itself. The wire of the bobbins of these electro-magnets are rather large, and the number of the turns is not very considerable.

We said in commencing this article that at the moment when the current was interrupted, the soft iron bar within the bobbin immediately loses its magnetism and returns to its neutral state. This is not absolutely true. The bars of the electro-magnets always retain, after the discontinuance of the current, a feeble magnetic power, of which the intensity and duration can be considerably diminished, but which it is impossible to completely prevent. The qualities of the iron have much to do with this matter. The better it is wrought, and the softer the iron, the less permanent magnetism will it retain, and the more rapidly does the complete demagnetization take place. Experience shows, besides, that the immediate contact of the iron armature with the poles of the electro-magnet power fully contributes to increase the intensity and the duration of the permanent magnetism; a slight sheet of paper put between the poles of the magnet and the armature is sufficient to hasten considerably the demagnetization of the soft iron bars.

In the construction of relay-magnets and sounders, too much care cannot be taken to diminish the effect of permanent magnetism. This is the only means to obtain electro-magnets, which can produce very rapid oscillations upon their armatures, and thus communicate signals rapidly.

The rapidity of telegraphic correspondence depends, in a great measure, upon the speed with which the soft iron bars become magnetized and demagnetized under the influence of the alternate passage and interruption of the inducing currents.

Consequently, iron as soft as possible must be selected for constructing the bars of electro-magnets, and care must be taken to regulate the play of the movable armatures, in such a manner that they can never come in direct contact with the poles of the electro-magnet.

INDUCED CURRENTS.

In 1832, Prof. Faraday discovered that an electric current or a magnet is able by induction to develope at a distance electric currents in a conducting wire, just as a body charged with static electricity electrizes an insulated conductor by induction. The following is the mode by which this remarkable result is obtained:

We wind round a wooden cylinder two silk-covered wires, so as to make two perfectly similar helices, the spirals of which are parallel, and as near to each other as possible. The two ends of one of the wires are made to communicate with a galvanometer, and the two ends of the other with the two poles of a battery. At the moment when this latter communication is established, the first having been established previously, the needle of the galvanometer is seen to deviate; but this deviation immediately ceases, even though the current of the battery continues to circulate. As soon as this current is interrupted, the needle of the galvanometer a second time experiences a sudden and more permanent deviation; but this deviation occurs in a contrary direction to that in which the former had occurred. Thus the voltaic current that traverses one of the wires determines in the other an instantaneous current at the moment when it commences to pass, and determines it in a second at the moment when it ceases to pass. These two currents are called *induced currents*, and the current of the battery the *inducing current;* the induced currents, as we see, are instantaneous. Let us further add that the former has a direction contrary to that of the inducing current, and the latter a similar direction.

This experiment proves that when we suddenly bring near to a part of a conductor, forming a closed circuit, a conductor traversed by a current, we determine in the former an instantaneous current, moving in a direction contrary to that of the current brought near to it; and that when we remove it, we determine a second instantaneous current, moving in the same direction with the current that is removed.

The intensity of the induced current depends on many circumstances; first, on the length and diameter of the wires of the helices; and then on the energy of the inducing current, or the strength of the magnet. In general, it is advantageous to take very long wires, and even to add several helices end to end, one after the other; but if we are not producing the induction with a magnet, it is necessary to employ an inducing current arising from a battery of a great many pairs.

GAS LIGHTING BY ELECTRICITY.

A new patent apparatus for the instantaneous lighting or extinguishing of gas lamps has just been successfully tried at Preston, England, and is thus described in the *Engineer:* "The apparatus constituting the invention looks like a moderate sized globular inkstand of glass, surmounted by a tube of the same material, with a metallic top; and, by screwing off the burner, it can be very easily attached to any lamp, chandelier, pipe, or ordinary gas jet. The base or globular portion is filled with a deep red colored liquid—a simple chemical mixture, with no combustible properties, almost without smell, and so cheap that three pennyworth of it will serve one lamp for twelve months, Over this liquid, and within the glass tube, there is a plate of zinc, along with a piece of graphite or gas coal, and, between those and a thin coiled platinum wire fixed over the cap of the general vessel into which a gas burner is inserted, galvanic communication is obtained. A pipe, to be screwed to that up which the ordinary gas supply flows, runs through the base of the vessel to about the centre of the surmounting tube; pressure brought to bear upon the gas in this pipe causes, by small collateral openings, a simultaneous depression upon the chemical solution which occupies a lower level in two side tubes; the gas occupies the vacuum caused by the displaced liquid, and then ascends to a chamber in connection with the burner, while the displaced liquid is pressed into two side tubes effecting contact with the zinc and graphite, generating galvanic electricity, which is communicated to the platinum wire, and excites the catalytic power of the wire, which, when exposed to the ascending jet of gas, results in immediate, almost instantaneous, ignition. Each lamp requires one of these appliances, but, as stated, they are cheap, and the price of the requisite liquid may be termed nominal. The apparatus is virtually self-acting; it requires no skilled hands to superintend its operations; it may be attached by a novice; it may be replenished at any ordinary chemist's shop for a few pence per year; it needs nothing but fixing, and then being subjected to the simple action of gas pressure."

The idea of attaching a separate galvanic battery to each gas burner, for the purpose of igniting and extinguishing the gas, may be novel, but certainly it is complicated.

The method now extensively in use in this country is much better, and is as follows:

A galvanic battery is placed in the cellar, attic, or other convenient portion of the building, from which

Digitized by Google

wires extend to the gas meter, and also to each gas burner over the orifice of every one of which a fine platinum wire is arranged in such a manner as to form a part of the electric circuit.

In connection with the battery and wires two or more telegraph keys or buttons are employed, placed wherever convenience requires. By touching one of the keys the electric current is made to operate a magnet and lever which is attached to the gas cock, whereby the latter is turned and the gas either let on or shut off. By touching the other key the electrical current is made to pass through the several platinum wires on the burners, thereby almost instantly heating the platinum up to a nearly white heat and igniting the gas. It is a pretty sight to witness the sudden ignition of the jets of a large chandelier in this way.

This plan of lighting, first practically applied by Professor Samuel Gardner, is employed for lighting the great dome and other apartments of the Capitol at Washington. Stewart's store and dwelling, and Booth's Theatre, New York, and, in fact, hundreds of buildings, public and private, in various parts of the country, are electrically lighted in this manner, and the success of the system will now make its employment general.

BREVITY IN DESPATCHES.

The despatches which pass over a telegraph line in the course of a year, if collected together, would present a very curious and interesting volume of correspondence. The price of the transmission of a message depending upon the number of words which it contains, of course renders the construction of it necessarily as brief as possible. Most despatches are contained in less than ten words, (exclusive of address and signature, which are not charged for,) and it is surprising how much matter is often contained in this brief number. Among the best examples of brevity which we have met with, however, are the two following.

A lady in a neighboring city, desirous of ascertaining when her husband would return home, sent him a message making the inquiry; to which he responded, that important business detained him, and that he could not leave for some days.

The lady immediately replied by sending him another despatch in the following laconic manner:—

"To F. C. P.—Despatch received. Deuteronomy xxiv, 5. (Signed,) "KATE."

The gentleman to whom the despatch was addressed, upon referring to the passage in the Scriptures alluded to, obtained the following lengthy and suggestive epistle :—

"When a man hath taken a new wife, he shall not go out to war, *neither shall he be charged with any business:* but he shall be free at home one year, *and shall cheer up his wife which he hath taken.*"

The second example is the reply sent to a person in a distant city, who, having committed some offence against the laws, and run away, was desirous of ascertaining if it would be prudent for him to return. He therefore telegraphed in the following laconic style :—

"NEW YORK, July 4.

"To B. C. M.——, Philadelphia.
"Is everything O K ? "D. T. M."

To which he obtained the following reply:—

"PHILADELPHIA, July 4.

"To D. T. M——, New York:—Proverbs, chap. xxvii., 12.

Upon reference to the passage indicated, the inquiring individual obtained the following advice, which, it is to be presumed, he followed:—

"A prudent man foreseeth the evil, and *hideth himself;* but the simple pass on, and are punished!"

NOTE.—Sweden jointly operates certain offices in connection with neighboring countries, as for example :

With Denmark, at Copenhagen, where two Swedish employees are stationed.

With Germany, at Malmo, in Sweden, where nine German employees are stationed.

With Russia, at Haparanda, in Sweden, where one Russian employee is stationed.

With Russia and the Grand Northern Telegraph Company, at Nystad, in Finland, where one Swedish employee is stationed.

Sweden owns, jointly with Prussia, the trans-Atlantic cable laid down in 1865 between Skare, in Sweden, and Arcona, at the Island of Rugen. The length of this cable is forty-five miles.

Also the cable laid in 1862 in the Sound, between Huesborg, in Sweden, and Vedbek, in Denmark, belong in common to those two kingdoms. The length of the cable is 9.5 miles.

In October, 1872, a joint Swedish-Norwegian office will be established at Christiania, the capital of Norway, where two Swedish employees are to be placed.

VARIOUS UNITS OF ELECTRICAL RESISTANCE.

Wheatstone's Unit.—To Prof. Sir Charles Wheatstone is due the credit of having constructed (in 1840) the first instruments by which definite multiples of a resistance unit could at will be added to, or subtracted from, a given circuit. The standard resistance unit which he proposed and employed, was that of 1 foot of copper wire, weighing 100 grains.

Jacobi's Units.—Professor Jacobi of St. Petersburg has made various suggestions for units of electrical resistance. The unit which is commonly known as Jacobi's Unit, and of which he sent copies to various physicists; was made of a length of 25 feet of a certain copper wire, weighing 345 grains.

Another proposition of Professor Jacobi was to employ as unit of electrical resistance that of a copper wire 1 metre long and 1 millimetre diameter.

Siemens' Mercury Unit.—This unit represents, according to the definition of Dr. Werner Siemens, the resistance of a prism of pure mercury 1 metre long and 1 square millimetre section at 0° C.

This Unit was first produced in 1860, and resistance coils in German silver wire were adjusted from it. A reproduction of the normal resistance tubes, in 1863, was found to agree within 0·1 per cent. with the results originally obtained. An error, arising from the specific gravity of mercury having been taken as 13·557 instead of 13·596, was corrected in 1866, so that all Siemens' resistance coils issued previously to that date are 0·29 per cent. too great. That is to say, the resistances which are marked as 1, are really 1·0029 mercury units, and the end results have to be multiplied by this constant (1·0029) in order to be expressed in mercury units according to the definition. One Siemens' Unit = 0·9536 ohms.

French and Swiss Units.—In the Telegraph Administrations of France and Switzerland, the unit of the electrical resistance coils in use for some time previous to 1867, was equivalent to the resistance of a length of one kilometre of the iron wire employed for the telegraph lines, 4 millimetres diameter. As no very exact measurements are required to be made of overhead lines, these units were not either defined or produced very exactly, and no temperature was given to enable a reproduction of the units if it should have been deemed desirable. Consequently, the unit coils of the Swiss ateliers, and those of Bréguet and Digney, differed amongst themselves as much as 15 per cent. In 1867 both Bréguet and Digney readjusted their units to one-tenth of a mercury unit, which is very nearly their original value. In all French submarine cable work, resistance-coils adjusted to the mercury unit are employed.

Matthiesen's Unit.—This unit was defined as the esistance of a statute mile of pure annealed copper wire one-sixteenth of an inch diameter, at 15·5° C.

Varley's Unit.—This unit obtained considerable employment in cable and line work of the E. and I. Telegraph Company. Mr. Varley originally constructed it from a statute mile of special copper wire one-sixteenth of an inch diameter; but afterwards readjusted it to twenty-five mercury units.

German-mile Unit.—The first unit of measurement used in the telegraph service in Berlin was that of a German mile (8,238 yards) of copper wire, its diameter being one-twelfth of an inch, and its temperature 20° Cent. Resistances adjusted to this unit were manufactured, as early as 1848, by Messrs. Siemens & Co., but have been long since superseded in Prussia by coils adjusted to the mercury unit.

THEORETICAL HYPOTHESES.

Two great hypotheses have been proposed for explaining electric phenomena. One of them, proposed by Franklin, and adopted by Cavendish, Cavallo, Beccaria, Æpinus, Volta, and others, is still employed by some philosophers; the other, proposed by Symmer, and adopted by Coulomb, Poisson, &c., is more generally employed by writers on electricity at the present time.

Franklin admitted the existence *of a solitary electric fluid*, acting by repulsion on itself, and by attraction on all ponderable substances. According to this hypothesis, this fluid is spread over all substances in nature; and in order that electric equilibrium should exist between any body and the bodies which surround it, each of them must contain a certain quantity of electricity, depending upon its mass and nature. The friction and other means of electrization act, by increasing or decreasing the quantity of electricity which the bodies contain. A substance is positively or negatively electrified, according as it contains a quantity of electricity superior or inferior to that which corresponds to this neutral state or equilibrium. Notwithstanding its seeming simplicity, this hypothesis of Franklin does not adapt itself very easily to the explication of the attractions and repulsions remarked between electrified bodies.

In Symmer's hypothesis the existence of two electric fluids is admitted. One of them is developed upon polished glass, when rubbed with wool, which is called the *vitreous or positive fluid;* the other is developed upon a stick of rosin, when rubbed with wool, which is called the *resinous or negative fluid.* Each of these imponderable fluids is formed by molecules, which repel each other, while the molecules of one attract the molecules of the other. In conducting bodies these fluids move freely, and their molecules, obedient to their mutual repulsion, accumulate upon the surface, where they are retained by the resistance which the air, in its quality of an isolating body, opposes to their displacement. The molecules of non-conducting bodies do not allow of the displacement of the electric fluids which remain located in the parts where they have been developed. Two equal quantities of positive fluid and negative fluid, brought face to face, are obedient to their mutual attraction—combine together and reconstruct the neutral or natural fluid. This neutral fluid exists normally in every body in nature, but its presence is not manifested by any exterior phenomenon, on account of the opposite properties of its two constituent elements.

The action of friction, and of other means of electrification, are confined to a decomposition of *neutral* fluid; one of the bodies becoming charged with *positive* electricity, the other with *negative* electricityt and the elementary fluids, thus liberated, manifes, their presence by the usual phenomena of attraction and repulsion.

The ideas of Symmer on the composition of neutral fluid, and on the *modus operandi* of the various processes of electrification, agree with the results supplied by the two following experiments:

1st. If two bodies are rubbed against each other, as long as the contact lasts, it is impossible to ascertain any sensible sign of electric reaction; but the moment that the two bodies are separated they are both electrified, one of them negatively, the other positively.

2d. Two balls of elder pith, isolated and charged with the same quantity of opposite fluids, attract each other; but the moment they touch no trace whatsoever of electrification is preserved, and they resume the natural state.

In the actual condition of science many objections arise against Symmer's hypothesis, but the theory of the two fluids has the great advantage of being easily adapted to the exposition and classification of observed facts. It seems to us that it ought to be preserved not as an admitted fact, but as a conventional term. In fact, experience shows that, under the influence of friction, chemical action, heat, &c., the surface of contact of the two bodies present becomes the seat of a special power, which develops in these bodies two *opposite forces*, but nothing positive has been taught as to the *nature* of these forces. The expressions, *positive fluid and negative fluid*, consequently, ought to be accepted only as a means to denominate these forces, and at the same time to indicate that their actions are opposite to each other.

COMPARATIVE TEST OF INSULATORS.

NEW YORK, Sept. 26, 1872—10 A. M.

	65 Cups Z. Deflection of Needle.	85 Cups P. Deflection of Needle
Pond	½ degree.	¾ degree.
W. U. Glass	8½ "	11 "

NEW THEORY OF TERRESTRIAL MAGNETISM.—Professor Zollner proposes a new theory in regard to the origin of terrestrial magnetism. He adopts the idea of drift currents upon the liquid surface of the sun, by means of which he tries to explain the movement of the sun spots. These drift currents originate, according to his conception, from the current of heat continually ascending from the interior, and from the rotation of the sun. Such currents, Professor Zollner maintains, exists in all rotating cosmical bodies, even after the surface, cooled by radiation, has become rigid to a certain extent. This is the case with the earth, and the continuous regular currents of the interior liquid mass produce different effects upon the outer shell, mechanical, thermal, and also magnetical, the latter as a necessary consequence of the electricity originated by the currents. The professor further maintains that by this hypothesis the general phenomena of terrestrial magnetism may be satisfactorily explained, and that they are related to the currents of the inner liquid mass, and whatever effects these currents, as, for instance, volcanoes, reacts immediately upon the magnetism of the earth. Whenever a cosmical body becomes entirely solid, no induced magnetism can exist, etc — *Harper's Magazine for September.*

MISS CAROLINE SMITH has favored the world with a rhymed *expose* of the deep-laid plans of our telegraphic companies. As to the future, she darkly suggests:

> And is not this their object your rights to tear down,
> And control a free suffrage through country and town,
> And to secretly gain such political power
> As may serve their dark purpose at some future hour?

The evils of the present consist in the well-known noises produced, according to the authoress, by the dispatches passing over the wire:

> The sick and the helpless are doomed now to hear
> The incessant loud ring from the posts far and near,
> And unless they 're removed in due time from the noise,
> It endangers their life or their reason destroys.

Miss Smith wishes the press to demand the destruction of all telegraph lines, and especially of those which pass through her town. As she has cunningly concealed the name and location of the town, we cannot comply with the latter part of her request

Emerson says that every man or woman who is intellectually well is a poet.

FOREIGN TELEGRAPHIC ITEMS

The directors of the India Rubber, Gutta Percha and Telegraph Works Company have announced an *ad interim* dividend at the rate of five per cent.

The receipts of the Great Northern Telegraph Company's European lines amounted for the month of August to 131,606fr. (£5,264), and for August, 1871, to 106,612fr. (£4,264), showing an increase of £1,000. The traffic receipts on the China and Japan lines for the month of July amounted to 97,485fr. (£3,899), against 61,245fr. (£2,450) in July, 1871, showing an increase of 36,240fr. (£1,449). In consequence of interruptions on the Siberian land lines the traffic returns for the month of August had not yet arrived from China and Japan.

Advices from Buenos Ayres announces the inauguration, on the 29th of July, of the Transandine Telegraph, connecting the River Plate with the Pacific, the works of which were commenced in November, 1870. Senor Sarmiento, the President of the Argentine Republic, declared a national holiday on the occasion, and the ceremony was attended by the foreign ministers and consuls and all the principal persons in Buenos Ayres, including Mr. Wheelwright, who was the first introducer of the telegraph system into Chili. As the Brazilian line with Montevideo is nearly finished, Valparaiso and Buenos Ayres will soon be within fourteen days' communication with Europe, and next year, when the cable shall have been laid between Brazil and Europe, the chain through South America will be complete and instantaneous.

The total number of messages forwarded from postal telegraph stations in the United Kingdom, during the week ending August 31, 1872, was 320,920, an increase over the corresponding week of last year of 64,811.

The *South Australian Register* states that by the middle of June the Superintendent of Telegraphs calculates that not less than 150 miles would remain unconstructed. A despach has been received from Tennant's Creek, announcing the arrival of Mr. Lewis and party with their horses, on the 24th May. The remainder of the express party were expected to reach Mr. Patterson, at Daly Waters, on the 7th June. The Telegraph Department at Adelaide is now communicating with Tennant's Creek Station, a distance of 1,400 miles, as easily as with Melbourne.

The proposal made in the Assembly Cape Parliament, South Africa, to place the sum of £75,000 for the extension of telegraphic communication to the Diamond Fields, has been carried.

At a special meeting of the Chamber of Commerce, held at Port Elizabeth, on Wednesday last the Committee highly approved of the idea of bringing this Colony into telegraphic communication with Europe and the East by marine cable, *via* Mauritius, and engaged to support any practical scheme which might be suggested, having in view the landing of the cable at that port. The Committee were of opinion that the terminus of the cable should be fixed in Port Elizabeth, because this is the most centrally situated part in the Colony, and is also the chief emporium of trade in South Africa.—*Eastern Star, Graham's-town, July* 9, 1872.

We learn from the report of the Superintendent of Electric Telegraphs in Queensland, that at the close of last year there were fifty-one stations and 2,614½ miles of wire in the Colony; since then new lines have been completed from Wes Westbrook to Warwick, from Claremont to Springshire, and from Warwick *via* Leyburn and Inglewood to Gondiwindi.

CORRESPONDENCE.

To the Editor of the Journal of the Telegraph:

Would an operator, receiving a message for a party, with wrong address, but knowing who it was from, and their agent in this place, be justified in delivering to said agent, (with note of explanation), where it would take from one to two hours to have it corrected?

Answer.—It would be proper to obtain the correct address.

To the Editor of the Journal of the Telegraph.

If we receive a "red" message for a party, and cannot deliver it the next morning, the party being out of town, and we are therefore requested by his clerk to forward to him, how should we forward it from this office—at full or half rate? S.

Answer.—When you have delivered a message to the place of business of the party addressed, you have performed your whole duty. If the person to whom it is addressed is out of town, and his agent wishes it forwarded to him, he should state whether it should be sent at full or half rate.

In our issue of August 15th, 1872, the following inquiry was made: "Suppose a message to be left at an office on the morning of July 27th, dated 26th, the sender having paid for it and gone, must the message be transmitted as taken, or should the operator correct the date?" To which we replied, "That the operator should, in sending, state that it was filed on the 27th."

We should have added, however, that the receiving clerk should not take a despatch so dated, but that he should have required the customer to change the date when it was handed in, and thereby save the explanation or statement that it was filed on the 27th, and also, very probably, save a check error.

In the same issue the following query was put: "Suppose I receive a message August 1st, dated San Francisco, July 31st, must I include that message in August report, having sent in report for July?" To which we replied, "Yes, with special explanations."

We desire to call especial attention to the custom indicated by the above inquiry, as a cause, among many others, of the heavy, wearisome, profitless, nay, even unnecessary, labor of the check department. The person who put the above inquiry apparently closed his report when he closed his office on the night of the 31st, thinking that when *his* light was out that work was over for every one else; whereas, he should not close his report till the end of the second day of the ensuing month, in order that he may include in it delayed business. The books should not be closed on any day until there is a reasonable assurance that all back business is in.

Greenville is informed that when the two terminal offices on one wire are sending and receiving at the same time with the duplex apparatus, no intelligible signals will be produced upon an intermediate instrument.

Operator at Boston is informed that the letters Ahr, used at the commencement of a message, is an abbreviation of the word another.

Inquirer will find in the JOURNAL of September 16, full and explicit information in relation to the use of the new tariff book.

There are twenty-one words in the following message:

"Will be in Carthage at three P. M. Can you serve process in Dallas City to-night. Answer to T. W. & W. Junction."

Names of cities and places, when used to designate such cities and places, will be counted as one word. Dallas City is the name of a place, and is published as such in the Post Office Directory and in Lippincott's Gazetteer. T. W. and W. Junction is not the name of a place, within the meaning of the rule, but merely the description of a thing or of a location in a place, and is, therefore, to be counted for as many words as it contains.

TELEGRAPHY IN FRANCE.

Some statistics of telegraphic administration in France, recently collected and made known by M. Blavier, afford information of interest. The service is carried on by three distinct classes of employes; the general staff, the staff for maintenance and repairs, and the telegraphic clerks. The *etat-major* is composed of a Director, 3 Inspectors-General, 10 Divisional and 69 Inspectors.

In 1871 there were 41,248 kilometres of aerial lines, with about 119,405 kilometres of wires: also 571 kilometres of submarine cables, and 18½ kilometres of pneumatic tubes; making a total length of 41,837½ kilometres (26,000 miles), constructed at a total cost of £1,468,000, inclusive of the Algerian cables. There were 3,253 offices open, inclusive of 1,228 at railway stations, divided in three categories, viz.:—

1. Principal bureaux, about 200 in number, despatching not less than 140 to 150 messages daily, and employing from 4 or 5 to 25 or 30 clerks.

2. Secondary bureaux, about 350 in number, mostly situated at the chief town of the arrondisement, and concentrating the services of the next class.

3. The cantonal, municipal, and semaphoric bureaux, &c.

In 1870 the total number of messages forwarded amounted to 5,663,852, of which only 5 per cent. exceeded 20 words in length.

The annual cost of a kilometre of aerial line, comprising interest and maintenance, was 14 francs (about 18s. per mile); and the expense of a single despatch per kilometre was about the 800th part of a franc, equivalent to the rate of 133⅓ miles for a farthing.

Experience has shown that a few days' practice suffices for the acquisition of the power of working the needle telegraph; whereas three months' study is required before familiarity with the Morse apparatus is attained. For rapid transition (18 to 20 words per minute), for deciphering a despatch by the ear, and for a thorough mastery of the manipulation of the Hughes apparatus—the qualifications of a skilled operator—several years of uninterrupted practice are found necessary.

AN improved and more rapid method of telegraphic printing has been invented by Mr. R. Herring, who having been applied to by a Mr. Franklin for a means of sending phonetic signs by telegraph, he wishing to be able to print four symbols simultaneously, either all dots, all dashes, or any combination of the two; Mr. Herring found it would be possible to accomplish this by attaching eight keys to a modification of his present instrument, so arranged that four batteries, by means of four wires, should control four inking dials like that now in use.—*Mechanics' Magazine.*

Journal of the Telegraph.

This Journal is issued on the 1st and 15th of each month. Its circulation is 6,500. It goes to every State, Territory and Province on the Continent. It is fast becoming a necessity, and is already welcomed as a friend. No better medium for advertising exists.

TERMS:

ONE DOLLAR PER ANNUM IN ADVANCE.

FOUR DOLLARS FOR FIVE COPIES.

Address—

JOURNAL OF THE TELEGRAPH,

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, OCTOBER 1, 1872.

THE TELEGRAPHERS' ASSOCIATION.

In the last number of the JOURNAL we published the Address and Constitution of the Telegraphers' Association, the successor of the Telegraphers' Protective League, an organization which was gotten up for the purpose of securing within the grasp of a few designing men the control of the vast Telegraph interests of the country, and which was made use of for inaugurating upon the lines of the Western Union Company one of the most unjustifiable and reprehensible strikes ever attempted, and which, had it been successful, would have ruined the Telegraph business of the country, and caused irreparable injury to every branch of industry.

The designs of the authors of the present scheme are somewhat more cleverly disguised than they were in the former one, but no thoughtful person of average discernment can fail to perceive that they are identical. Under the guise of a pretended solicitude for the interests of the employés of the various Telegraph companies, its authors seek to obtain as before, the control of the entire telegraphic fraternity of the country. There is very little probability that the sophistical arguments of the chief managers of the present secret society can again deceive any of those who were thoughtlessly inveigled into the former one, and thereby induce them to joint the present organization; but they may succeed in deceiving some well intentioned but unreflecting persons not connected with the former organization, and induce them to join the present one from a mistaken idea of its purposes and tendencies. To such persons we commend the careful consideration of the following extracts from the Constitution of the Society, which shadow forth the real purposes of the originators and promoters of the plot:

"It shall be the duty of every member of the Association to cheerfully *acquiesce in all measures that may be duly initiated by the Council to which he belongs. The firm and unswerving loyalty of every member is the foundation of power, which must be maintained at all hazards.*

"The Association expects every member to perform his whole duty towards his employers, in accordance with the terms under which he was engaged, *provided he does not thereby conflict with a duly authorized order from the Councillor of the Council to which he belongs.*

Every candidate is required to bind himself not to reveal the names of the officers, or members, or the purposes of the Association, and to obey all orders issued by its officers.

It seems almost incredible that any intelligent man should be willing voluntarily to pledge himself in advance to blindly and unquestionably obey any order from any source whatever, but much more so that he should agree to obey the order of a secret and irresponsible organization, the purposes, instructions and acts of which he can have but a limited knowledge. What would be thought of the foresight of a man who should sign his name to a blank piece of paper and give it into the hands of a stranger to make such use of as he thought proper? But how much better is the prudence of the man who pledges himself solemnly to obey without question the mandate of a secret band of conspirators? How can any honest man engage to perform a service for one person, and then secretly bind himself to break such engagement whenever ordered to do so by another? And yet this is precisely what every member of this League solemnly promises to do.

When the former League culminated in the strike of three years ago, it transpired that the leading spirits engaged in it were in the employment of competing companies, the head centre being the manager of one of the city offices of a competing line. The rank and file were to some extent made up from the employés of the Western Union Company, while the officers were largely composed of persons in the employ of other companies. As stated in the address of the officers of the Company at the time, "the employés of the Western Union Telegraph Company, by joining an organization thus officered, have put themselves in the situation of an army which, by solemn and secret conspiracy, should bind itself to lay down its arms and surrender its cause at the bidding of and upon the signal of the commander of the enemy's forces."

No employé of the Company who has any respect for his reputation, or any regard for common honesty, will have any thing to do with this organization. It can under no circumstances do him any good, and may result in much harm. No company could knowingly accept the services of men who have pledged themselves to obey the mandate of such an organization, nor can any honest man engage himself to work for a company and conceal the fact of such an obligation as that required to be taken in joining the Telegraphers' Association.

When messages are received for delivery by special messenger, pains should be taken to have the service performed at the least possible cost; this, and no more, is to be charged for the service, and upon no account are Managers allowed to receive from messengers part of the delivery charge. This rule is imperative.

THE CINCINNATI EXPOSITION.

The Exposition now in progress in Cincinnati is, undoubtedly, the greatest ever held in the United States. While the articles on exhibition are entirely the product of American skill and industry, and chiefly that of the West, yet from its magnitude and importance it must take rank hardly second to the great International Expositions of London and Paris.

Profiting by the experience of former years, the management have erected new buildings surpassing in extent any heretofore erected in the United States for a similar purpose, and comprising an exhibiting space of about seven acres. In the arrangement of the various departments the convenience of both exhibitors and visitors has been carefully consulted, and an improved distribution of articles into groups adds largely to the general symmetry of the Exposition. A handsome fireproof structure, 62 by 160 feet, detached from the main building, is devoted to the Fine Arts department. The display of paintings, many of them of great value, of photographs and lithographs, is very fine.

Columns might be filled in the description of the various articles upon exhibition; but as it is with electrical and telegraph machinery that our interest chiefly lies,—the description is confined to that portion of the particular department in which these are to be found.

The Western Union Telegraph Company have on exhibition a splendid stock of telegraphic apparatus, embracing relays, sounders, and keys. They also exhibit the improved duplex instrument. There is no doubt that Mr. Stearns will be awarded the medal for this latter instrument as being the greatest improvement in telegraphy.

The Gold and Stock Telegraph Company exhibits the only perfect automatic printing telegraph instrument—that invented by Mr. G. M. Phelps. They also show a pair of Edison's Universal Printers for private lines, and a pair of Gray's Printers for the same purpose.

The Western Electric Manufacturing Company have a fine display of all kinds of telegraph machinery and supplies.

Mr. E. G. Gilliland, of the Western Union office in Cincinnati, who is in charge of the machinery above mentioned, exhibits a small Sounder and Key for students and short lines, for which it seems well adapted.

Selden's Automatic Stock Printer is exhibited by Mr. E. C. Armstrong.

F. L. Pope & Co., of New York, exhibit their "Nonpareil" instrument and attachments. Also the electrical railroad signals invented by the head of that firm. These signals, by the way, are something better than the average of such productions, and have been adopted by the Pennsylvania Central Railroad Company, and doubtless will shortly be in general use throughout the country.

H. D. Rogers & Co., of Cincinnati, have a case well filled with telegraph apparatus of various kinds, the only novelty noticable among them being the Rogers-Gilliland Dial Machine. This is a very simple and cheap instrument. It has a step by step motion and is worked by an ordinary Morse key.

The Putt Mechanical Instrument, for students, is also on exhibition. This instrument is too well known to need description in these columns.

Several "Burglar Alarms," and numberless magnetic instruments for medical purposes, are also on view.

There is considerable telegraph business transacted at the fair. The telegraph office in the building (of

Digitized by Google

course Western Union) is in charge of Master John McCabe, a gentleman who has safely matured thirteen summers. The writer has seen many worse operators of far greater pretensions, old enough to be this lad's father.

The number of visitors to Cincinnati, attracted by this Exposition, is immense; and the beneficial results to the city, at present and to arise, is hardly within computation.

It is announced that the Exposition will remain open to the public until Saturday, October 5, but its success proving so great, it will doubtless be continued to a much later day.

THE VIENNA EXPOSITION.

The Universal Exposition to be held at Vienna, Austria, next year, promises to be much larger and more comprehensive than the similar exhibitions held in London and Paris. The great building is advancing toward completion. The first of July was the last day for receiving applications for space on the part of exhibitors. It is said that 15,000 Americans will send articles to this exhibition. This exceeds by several thousands the number of English exhibitors at either of the exhibitions held in London. It also exceeds the number of French exhibitors at the Paris exposition. Among the requests for space at the Vienna fair, 3,000 came from Hungary, 8,000 from the North German Empire, and 800 from Belgium. Each of the Grand Divisions of the earth, and nearly every county in each of them will be represented. It is said that the agricultural implement makers in this country will make an immense display, partly with a view of introducing their machinery to the favorable notice of the farmers of Eastern and Central Europe.

PRIVILEGED TELEGRAPH COMMUNICATIONS.

The secrecy of the telegraph has been on trial in California. In a San Francisco court, the Superintendent of the Western Union Telegraph Company appeared in answer to a subpœna requiring him to produce a book in one of the telegraph offices, containing copies of certain messages transmitted to San Francisco, to be used in evidence in a trial. The counsel for the Superintendent, Mr. Gamble, argued that this was an attempt to extend the power of subpœnas beyond legal limits. If the witness *were the custodian of the book he is forbidden by the law providing for the secrecy of telegraphic dispatches from revealing its contents.* The book-holder is to be summoned, and the judge is going to take the matter into consideration as to how far telegraphic secrecy is obligatory. The question whether certain communications to telegraph companies are, or not, what are technically known as "privileged communications,"—which the law has always held sacred from disclosure,—has heretofore arisen, collaterally, in a few instances in other States. We do not recall, however, that the question ever became of enough importance to invoke the authority of appellate courts,—*i. e.* of the last resort,—to settle it, although it may, likely enough, have been abjudicated. Generally, the proof relief upon as shown by and in the communications, has been found *aliunde* and by more direct testimony.

AMONG the pensions granted by the British Government during the year ending the 20th of June 1872, was one of £100 per year to William Fothergill Cooke, for services in the telegraphic system.

THE Western Union Telegraph Company will use over 150,000 miles of telegraph wire this year.—*Workingmen's Advocate.*

Wonder where they got that little item from.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York,
October 1, 1872.

To all Offices on W. U. Lines:

Hereafter, in the arrangement of the tariff circular, a statement of the changes in rates, names of offices, general information and names of new offices, &c., will be given in such a manner as shall render the entry of the same in the tariff book a work of much less labor and difficulty than heretofore.

Under the head of GENERAL INFORMATION, will be given all changes in rates, (except special rates) changes in names of offices, offices closed, changes in checking and general information *for each State*, arranged in the order in which the names of the offices are given in the tariff book.

Under the head of NEW OFFICES, new offices by States on W. Union lines and new offices on other lines, with tariff for the latter, will be given. Other lines offices will be designated by an asterisk. (*)

All notices given in the circular should be entered immediately upon the receipt of the JOURNAL, otherwise, confusion in checks and rates, and complaint from customers must be the result.

The following changes and additions have been made since the date of the last circular:

GENERAL INFORMATION.

Offices in Indiana, Kentucky, Michigan and Ohio will make the following change on their STATE RATES:

To Idaho Terr., $4.00. New Mexico Terr., $4.00.
Montana Terr., $4.00.

All offices in Central and Southern Divisions, except offices in Virginia, North Carolina and South Carolina will make their rate to squares 101, 110 and 129 equal to their rate to square 120 *if they are at present less than to that square.*.

That part of the INSTRUCTIONS relating to Half Rate messages, printed on page VI. of the new tariff book, which conflicts with *Executive Order No.* 141, published in last JOURNAL, is hereby revoked.

A NEW TELEGRAPH LINE BETWEEN ENGLAND AND NEW YORK.

The success attending Atlantic telegraphy has made people express wishes for more cables and reduced tariffs—the latter being so high as to be somewhat exclusive—and to enable the public to send messages at a less rate, the Great Western Telegraph Company was projected for the purpose of laying, during the course of next year, a cable from England to New York *via* Bermuda. This endeavor so far succeeded that the public took the matter up, and a contract was signed with Hooper's Telegraph Works for the manufacture and the laying of the cables, which are now in course of construction.

The following particulars are given in *Engineering:* The proposed route for the cable is entirely new. The cable will start from a convenient point at the Land's End to the Island of Bermuda, and from thence to New York. From Bermuda, a cable will in the course of time be laid to St. Thomas to connect with the network of West Indian cables, and there are subsequent intentions of connecting Bermuda with the coast of South America, which route is stated to possess the great advantages of connecting Brazil both with England and with New York by direct lines. The distances are as follows: Land's End to Bermuda, 3,225 knots; Bermuda to New York, 762; total, 4953.

In the existing Atlantic cables, the insulating medium is that of the well known aud generally used material, gutta-percha. In the present instance, however, the directors have decided to employ india rubber in that form known as Hooper's material, as the insulator for their cable. Hooper's core has of late years been largely adopted, as for instance, for the Persian Gulf cable, the various English cables belonging to the Great Northern Company, and more recently the China and Japan extensions. The success of the present cable, being the longest stretch of cable yet attempted, will prove of material moment in the great question of gutta percha *versus* India rubber.

Conductor.—The conductor consists of a strand of seven tinned wires of annealed copper of the best quality and manufacture, and the resistance of a nautical mile will not exceed 4·3 ohms at the standard temperature of 75° Fahr.; this represents a conductivity of 92½ per cent. of pure copper. The copper strand will weigh for this section 300 lbs per knot.

Dielectric.—The conductor will be insulated with material to the weight 250 lbs. per knot. This may be briefly stated to be pure rubber next the wire, a separating medium, then coatings of vulcanized rubber, and finally a jacket, the whole process being peculiar, but representing finally a compact insulated core.

The insulated conductor, or core, is protected with a serving of India rubber felt, and subsequently with a serving of jute yarn, in quantity according to the requirement of the various types of cable.

The manufacture of this cable progresses steadily. Sir William Thompson and Professor Fleeming Jenkin are electricians and engineers to the company.

We are again called upon to announce the death of two members of the Telegraphers' Life Insurance Association.

Fred. A. Randall, aged 21 years, (certificate No. 726,) died of inflammation of the bowels, at Ann Arbor, Mich., on Sept. 13th, after four months' illness. He was employed as operator in the Western Union office at Ann Arbor.

Andrew Ainsworth (certificate No. 850) died of consumption, at Greencastle, Ind., on Sept. 16th, after an illness of several months' duration. Previous to his death he was employed as operator at the depot office of the T. H. & I. R. R. Co. at Greencastle.

Notice is hereby given that the Annual Meeting of this Association will be held at 145 Broadway, New York, on Friday, the first day of November next.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 22. NEW YORK, OCTOBER 15, 1872. WHOLE NO. 119.

TANGENT GALVANOMETER.

Mr. Pouillet was the inventor of this apparatus, and was the first to make use of it to measure the strength of electric currents.

Upon a wooden table K K is (fig. 1) placed parallel to the plane of the magnetic meridian a circular ribbon of copper L L from 15 to 20 inches in diameter, 1 inch wide, and $\frac{1}{12}$ of an inch thick. This ribbon is surrounded by a silken thread and its two extremities are vertically bent so as to dip into two glass vessels filled with mercury V V′, connecting with the poles of a battery.

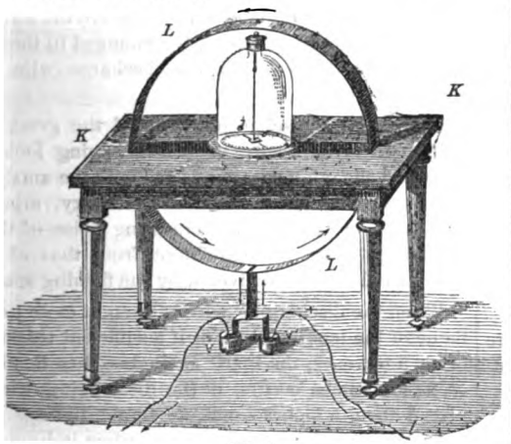

Fig. 1.

In the centre of the circle *a short and massive needle* is suspended, by means of a thread without torsion. A very light copper or wooden index *d*, perpendicularly fixed to the axle of the needle, indicates on a graduated horizontal scale the angular movements of the magnet.

When the current passes the needle is deviated; on account of the breadth of the copper ribbon L L, and the shortness of the needle, the resultant of the actions exercised by the cylindrical current on its poles is always nearly perpendicular to the magnetic meridian.

Consequently if we call *i* the intensity of the current, or its action on the needle placed in the plane of the magnetic meridian, this action will become $i \cos d$, when the needle has reached an angular deviation *d*. But in this position, the directive power of the needle equal and opposite to the action of the current is $f \sin d$. Thus we have:

$$i \cos d = f \sin d;$$

Whence

$$i = f \frac{\sin d}{\cos d},$$

Whence, finally:

$$i = f \text{ tang } d.$$

With this galvanometer, the strengths of the currents successively transmitted over a circuit bear the same relations as the tangents of the angles of deviation of the magnetic needle.

More recently Mr. Gaugain modified in a very successful manner the construction of the tangent-galvanometer, based upon the following theorem, deduced by Mr. Bravais from the formula of Ampère:

"If a magnetic needle is submitted to the action of a circular current set up in the plane of a magnetic meridian, and the centre of the needle occupies the apex of a right cone, having for its base the circular current, the tangents of the needle's deviations are almost absolutely proportioned to the strength of the current, if the height of the cone is equal to a fourth part of the diameter of the base."

Experiments show that with needles of 1¼ to 1½ inches in length, and circular currents whereof the radius is at least thrice the length of the needle, when the conditions which are enunciated in this theorem are fulfilled, the limit of the digressions do not extend beyond $\frac{1}{1000}$; an amount so insignificant that it may be altogether disregarded in practice.

By these means tangent-galvanometers may be constructed, which are at the same time very accurate and very sensitive, and the diameter whereof need not be more than 7 or 8 inches.

In these new tangent galvanometers (fig. 2) the magnetic needle, its index and its horizontally divided circle are carried by a stand P, which can be removed from or drawn nearer to the circular frame A, around which is rolled the insulated copper wire *t* and *t′*. The point of suspension of the needle is on a horizontal placed in the centre of the frame A perpendicularly with its median section, and at a distance from this centre equal to *a fourth part* of the diameter of the circular current.

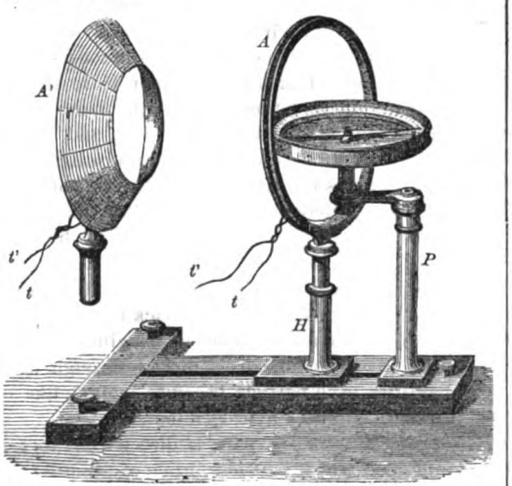

Fig. 2.

Mr. Gaugain, starting from the same principles, has constructed *tangent multiplicators*, by means of which the strength of the feeblest currents can be measured with great accuracy.

In fact, for a fixed position of the magnetic needle, the geometrical place of all the circles suitable for the formation of galvanometers is a straight cone, whose apex is in the centre of the needle, and whose angle is determined, the relation of its height to its base being known. If thus on the surface of this cone an insulated copper wire is rolled, and the current is transmitted through it, each convolution of the wire tends to produce a deviation of the needle, whose tangent will be proportional to the strength of the current. It is evident, that the *conical multiplicator*, formed by the reunion of these convolutions will possess the same properties.

In order to transform the tangent galvanometer into a tangent multiplicator, it is sufficient to detach the circle A from its stand H, and to have it substituted by the trunk of a cone A′, figure 2, on the outside surface whereof a fine insulated wire *t* and *t′* is rolled. These conical multiplicators are very sensitive, and very convenient for practical work. The centre of suspension of the needle must always occupy the apex of the trunk of the cone A′.

The modifications introduced by Mr. Gaugain in the construction of the tangent galvanometer renders his apparatus superior to all others for exact measurements.

Messrs. Knox and Shain, of Philadelphia, manufacture the Gaugain galvanometer with either one or two cones, as desired. Each cone is covered with two wires of equal size and length, so that the instrument may be used as a differential galvanometer, if desired.

Several of these instruments are employed in the service of the Western Union Company, and are found very useful and convenient, especially for measuring the internal resistance of batteries, for which, they are unequalled by any other apparatus in use.

CONSTANT QUANTITY BATTERY.

In a letter to the *Mechanics' Magazine*, Mr. H. Highton communicates the following as the result of his endeavors to find a constant quantity battery free from the objections attending the use of the Grove or Bunsen element. He says:—

"After a trial of numerous combinations to take effectually the place of a Grove or Bunsen battery, the fumes of which are so noxious, and of a Bichromate battery, which is both expensive and shows a good deal of polarization, I find the following the best combination.

For negative, carbon packed in granulated and peroxide of manganese with dilute sulphuric acid, say 25 per cent., and a little nitric and chromic acid, (or bichromate) added. The chromic acid absorbs the nitrate oxide fumes, and the combination readily takes the oxygen from the peroxide. I prefer a solution of common salt and zinc (or iron) for positive, as the salt is both more powerful than dilute acid, and prevents local action. It is well to have the cells of a good size. I am, &c.

H. HIGHTON.

Putney, September 16.

P.S.—I had the opportunity the other day of trying my telegraphic system on 150 miles of uninsulated wire under water, and found it presented no difficulty. I hope in a few days to try through 600 or 700 miles.

THE LAST NOVELTY IN PATENTS.—Three Chinese have taken out a patent at Paris for the invention of a new automatic and autographic continuous Telegraphic Instrument, by the aid of which apparatus the despatch is transmitted to the receiver as an exact fac-simile of the transmitter's autograph

SOME EXPERIMENTS WITH THE GREAT INDUCTION COIL AT THE ROYAL POLYTECHNIC.

BY JOHN HENRY PEPPER, F. C. S., ASSOC. INST. C. E.

The Large Induction Coil.

The length of the coil from end to end is 9 feet 10 inches, and the diameter 2 feet; the whole is cased in ebonite; it stands on two strong pillars covered with ebonite, the feet of the pillars being of a diameter of 22 inches. The ebonite tubes, &c., are the largest ever constructed by the Silver Town Works.

The total weight of the great coil is 15 cwts., that of the ebonite alone being 477 lbs.

The primary wire is made of copper of the highest conductivity, and weighs 145 lbs.; the diameter of this wire is 0·0925 of an inch, and the length 3770 yards. The number of revolutions of the primary wire round the core of soft iron is 6000, its arrangement being 3, 6, and 12 strands.

The total resistance of the primary is 2·201400 British Association units, and the resistances of the primary conductors are respectively—For three strands, 0·733800 B. A. U.; six, 0·366945 B. A. U.; twelve, 0·1834725 B. A. U.

The primary core consists of extremely soft straight iron wires 5 feet in length, and each wire is 0·0625 of an inch in diameter. The diameter of the combined wires is 4 inches, and the weight of the core is 123 lbs.

The secondary wire is 150 miles in length; it is covered with silk throughout, and the average diameter is 0·015 of an inch.

The total weight of this wire is 606 lbs., and the resistance 33,560 B. A. units. The length of the secondary coil is 50 inches, and the insulation throughout is calculated to be 95 per cent. beyond that required. The secondary wire is insulated from the primary by means of an ebonite tube of ¼ an inch in thickness and 8 feet in length.

The length of the secondary coil is 54 inches, the diameter is 19 inches, and without the internal ebonite tube containing the primary wire and iron core it is a cylinder 19 inches in diameter and 6 inches thick.

The condenser, made in the usual manner with sheets of varnished paper and tinfoil, is arranged in six parts, each containing 125 superficial feet, or 750 square feet of tinfoil in the whole.

A large and substantial made contact breaker, detached from the great coil and worked by an independent electro-magnet, was constructed and worked very well with a comparatively moderate power of 10 or 20 large Bunsen's cells; when, however, the battery was increased to 30 or 40 cells; it became unmanageable.

A Foucault break, with the platinum amalgam and alcohol above it, was now tried, and answered very much better than the ordinary contact breaker; there was no longer any burning or destruction of the contact points, although the great power of the instrument appeared to cause continued decomposition in the water of the alcohol placed above the platinum amalgam; and every now and then the spirit was violently ejected, probably by explosion of the mixed gases taking place in the amalgam, in which they collected in bubbles; the alcohol constantly took fire and had to be extinguished. A large and very strong glass vessel (in fact, an inverted glass cell belonging to a bi-chromate battery) was bored through, and the neck fitted into a cap with cement, a thick wire covered with platinum being inserted in the bottom; the platinum amalgam was poured on this, and over it a pint or more of alcohol; the contact wire was also very thick and pointed with a thick stud of platinum, and, being attached to a spring, contact was easily made and broken. Explosions did not occur, flashes of light could be seen between the amalgam and the alcohol, and the height of the column of the latter prevented the forcible ejection of the spirit, which no longer took fire. The break was used for eight hours in a continuous series of experiments.

The Bunsen's battery used in the experiments was made with the largest porous cells that could be obtained, and each cell contained about one pint of nitric acid.

Some experiments were tried with the battery arranged for intensity, and used with the complete condenser of 750 square feet of tinfoil and 1500 square feet of paper. At first five cells were used, and these gave a spark 12 inches in length. The number of cells were gradually increased until 50 were in operation, when a spark from 28 to 29 inches in length was obtained.

In order to ascertain whether any variation in the size of the condenser would effect the length of the spark, a number of experiments were tried; and it was found that when half the condenser was used, the spark increased in length up to twenty cells, but not after.

Experiments were now tried to ascertain whether any increase in the length of the spark could be obtained by arranging the battery and the primary coil for *quantity*, but no material advantage was obtained by this arrangement; even where three groups of cells were connected a decrease in the length of the spark is observed when compared with the 45 or 50 cells arranged for intensity, the difference being as 20 to 28.

The spark obtained from the large coil is thick and flame-like in its appearance, and therefore it will be alluded to as the "flaming-spark."

When the discharging point and circular plate are brought within 6 or 7 inches of each other, the flaming nature of the spark becomes still more apparent.

Two light yellow flames curving upwards appear to connect the opposite poles. If a blast of air from powerful bellows is directed against a flaming spark, the flaming portion can be blown away and increased in area, and thin wiry sparks are now seen darting through it, sometimes in one continuous stream, at another time, divided into three or more sparks, all following the direction in which the flame is blown.

The flaming spark is very hot, and if passed through asbestos (supported on an insulating pillar), quickly causes the latter to become red-hot.

When powdered charcoal is shaken from a pepper-box into the flaming spark in a vertical line and in considerable quantities, the greater part of the light is obscured, and the whole form of the flaming spark presents the appearance of a black cloud with a line of brightly ignited particles fringing the bottom parts. If the charcoal is dusted through in small quantities, each particle becomes ignited, like blowing charcoal into a hydrogen flame.

When the flaming spark is directed on to a glass plate upon which a little solution of lithium chloride is placed, the latter colors the flame upwards to the height of 3 or 4 in the most beautiful manner; and if the point of the discharge is tipped with paper, or sponge moistened with a little solution of sodium chloride, the two colors (the yellow from the salt, and the crimson from the lithium) meet each other, a neutral point being found about half-way, and thus illustrating apparently the dual character of electricity, and that + passes to − electrical, and *vice versa*.

The flaming spark can be obtained in perfectly dry air.

Whilst passing through common air, if blown against a sheet of damp litmus-paper, the latter is rapidly changed red. In order to ascertain whether the acid product was nitric acid, the flaming spark (9 or 10 inches in length) was passed through a tube connected by a cork and bent tube with a bottle containing distilled water, from which another tube passed to the air pump; on drawing the air slowly over the spark, and passing the former into the bottle, nitric acid was obtained in large quantities, so much so that it could be detected by the smell and taste, as well as by the ordinary tests. The popular notion that nitric acid is always produced during a thunder-storm would therefore appear to be correct. To determine the effect of a cooling surface on the flaming spark, a hole 1¼ inches in diameter was bored through a thick block of Wenham Lake ice, and the spark passed through the air in the tube of ice; no change took place, and the spark was still a flaming one.

When the spark was received on the ice, it lost its flaming character, and became thin and wiry, spreading out in all directions.

If the discharging wires were tipped with ice, the spark was always flaming when any thickness of air intervened between them. Even over the ice, if the spark passed a fraction of an inch above the surface, it was always a flaming one, but changed to the thin spark when the point of the discharge wire was thrust into the ice.

If one of the discharging wires of the great coil is brought to the centre of a large swing looking-glass and the other wire connected with the amalgam at the back, the sparks are thin and wiry, arborescent, and very bright; the crackling noise of these discharges being quite different from that of the heavy thud or blow delivered by the flaming spark.

When the discharging wire is brought close to the flame of the looking glass, or if a sufficient thickness of air intervenes, the spark again becomes flaming; or, as sometimes occurs, if the discharging wire is placed about 5 inches from the frame, the spark is party flaming and part wiry, *i. e.*, when it impinges on the glass.

The spectrum is a continuous one with the sodium-line.

When the blast of air is used, and the wiry sparks made apparent, then the nitrogen-line appears.

The flaming spark has been ascribed by some experienced observers to the incandescence of the dust in the air, and especially sodium chloride.

To ascertain whether the "flaming spark" could be obtained with a small number of cells, the large Bunsen's battery was reduced to three cells, and it was found that no appreciable spark could be produced when the whole primary wire was used with less than five cells.

By reducing the length of the primary wire, and using the four divisions separately, with five cells, the spark was wiry, and varied from 4½ inches to 6½ inches; with ten cells it was wiry, and varied from 8½ to 9½; in the latter the spark was slightly flaming. With fifteen cells the spark was slightly flaming, and varied from 10 inches to 11⅛ inches. With 20 cells a flaming spark varying from 11½ inches to 12½ inches was obtained.

When the two wires from the secondary coil are placed in water, no spark is perceptible, even when the wire was brought very close together, until they touch.

If the negative is passed through a cork, on which a glass tube (a lamp glass) is fixed containing a depth of 5 inches of water, and the positive wire is brought within half an inch of the surface of the water in the

Digitized by Google

tube, it becomes red-hot, and if drawn further away from the surface the upper part of the tube is filled with a peculiar glow or light abounding in Stoke's rays.

The experiments with the vacuum tube, and especially Gassot's cascade, are, as might be expected, very beautiful. When a coal-gas vacuum tube of considerable diameter, and conveying the full discharge from the secondary coil, is supported over a powerful electro-magnet axially, the discharge is condensed and heat is produced.

If placed equatorially, the heat increases greatly, and when the discharge is condensed and impinges upon the sides of the glass tube, it becomes too hot to touch, and if the experiment was continued too long the tube would crack.

The enormous quantity of electricity of high tension which the coil evolves, when connected with a battery of 40 cells, is shown by the rapidity with which it will charge a Leyden battery.

Under favorable circumstances, three contacts with the mercurial break will charge 40 square feet of glass.

On one occasion a series of twelve large Leyden jars arranged in cascade were discharged; the noise was great; and each time the spark (which was very condensed and brilliant) struck the metallic disk, the latter emitted a ringing sound, as if it had received a sharp blow from a small hammer.

The discharges were made from a point to a metallic disk; and when the former was positive the dense spark measured from 18½ to 18¾ inches, and fell to 8½ inches when the metallic plate was positive and the point negative.

Variations of the Leyden-jar experiments were tried by connecting the coil worked by a quantity battery of 25+25 cells with six Leyden jars arranged in cascade, and the spark obtained measured 8½ inches.

The same six jars connected with the coil, when the fifty cells were arranged continuously for intensity, gave a spark of 12 inches of very great density and brilliancy.

APPARATUS FOR THE PRODUCTION OF OZONE WITH ELECTRICITY OF HIGH TENSION.

BY PROF. ARTHUR W. WRIGHT.

Experiment has shown, that in the production of ozone by electricity, the maximum amount of oxygen is ozonised by the silent or glow discharge. In using the Holtz's electro-machine, the form of the apparatus usually employed must be varied to give good results.

When the poles of the machine itself are separated to a sufficient distance, the electricity passes between them, either in the form of a diffuse brush, spanning the whole interval, or with a very minute brush upon the negative pole, and a glow upon the positive, the intermediate space not being visibly luminous. This is the so-called dark, or silent discharge. When this occurs, the strong odor shows that a considerable amount of the atmospheric oxygen is converted into ozone.

If this discharge is made to take place in an enclosed space through which air or oxygen can be driven, the ozonising effect of the electricity is heightened and can be utilised. The apparatus which I have employed, and which has afforded very satisfactory results, consists of a straight glass tube about twenty centimetres long and having an internal diameter of 2·5 centimetres, the two ends being stopped with corks covered on the inner side with a thin coating of cement to protect them from the action of the ozone. Through the axis of each cork is inserted a glass tube of about 5 m.m. calibre and 7 centimetres in length, having a branch tube inserted perpendicularly at the middle, and long enough to permit a rubber tube to be slipped upon it. The outer ends of the tubes themselves are closely stopped with corks, through which are passed straight, thick copper wires carrying suitable terminals at their inner ends, and bent into a ring at the others. They are fitted so as to make tight joints, but to allow of motion in order to vary the distance between their ends. One of these wires carries a small ball; the other terminates in a disc with rounded edge, set perpendicularly to the axis of the tube, and so large as to leave an annular space of some two or three millimetres breadth around it. The gas is admitted through one of the branch tubes and escapes from the other, after having passed through the whole length of the tube.

In using the apparatus, the wires must be connected with the poles of the machine in such a manner that the disc becomes the negative terminal, as this arrangement gives the greatest degree of expansion and diffuseness to the current. On turning the machine and adjusting the ball and disc to a proper distance, a nebulous aigrette surrounds the latter, quite filling the interval between it and the wall of the tube, while the part of the tube between the disc and the ball is crowded with innumerable hazy streams converging upon the positive pole, or simply causing the latter to be covered with a faint glow. A current of air or oxygen sent into the tube must pass through this, and ozone is very rapidly produced, and in great quantity. The condensers are of course not used with the machine when this apparatus is employed.

NEW TELEGRAPH JOURNAL.

The new Society of Telegraph Engineers, in England, have commenced the publication of a journal, in which the progress of telegraphy as a science and as an art will be duly recorded. The first number contains a paper on "Automatic Telegraphs," by Mr. R. S. Culley, who thinks that, without the automatic apparatus, it would be impossible to supply the information required by newspapers all over the kingdom. "From the central station in London as many as 400,000 words are transmitted in a single night, and through five or six stations simultaneously, whereby it happens that the quantity of matter telegraphed is equal to a thousand columns of the London *Times*. All this is accomplished while one-half of the world are asleep. The rate of transmission varies: To Aberdeen, it is 60 words a minute; to Sunderland, 90; while to Manchester Liverpool, and Cardiff, it is 120. The messages are punched in strips or ribbons of paper, and these can be multiplied to any extent when pressure of newspaper work requires. The punching of the strips is greatly facilitated by the use of a pneumatic apparatus, in which the levers are struck by pistons actuated by compressed air. Three keys, like those of a pianoforte, open the valves, and the touch is so light that three or four ribbons can be perforated at the rate of forty words a minute, by a female clerk."

It would appear from the foregoing that our English telegraphers have not yet acquired the art of sending messages in the quickest and most economical manner, and they have something yet to learn. The aggregate number of words transmitted at the central office of the Western Union Telegraph Company, in this city, exceed that of the London central station, but no "punched strip" or automatic machines are employed in the New York office. Experience shows that the interposition of the punched strip, the punching machine, and the girl to do the punching, are an unnecessary complication in the sending of a telegraph message. First class operators can send messages more economically and quickly by the usual instruments than is possible by the above "automatic" plan. The rates of speed mentioned above, we believe, are equaled, if not exceeded, at the Western Union Telegraph office here.—*Scientific American.*

SOMETHING FOR NOTHING.

The terrific *expose* of the affairs of the Great Western Telegraph Company, published in our Sunday issue, in the crushing shape of a Supreme Court decision by Judge Lawrence, will cause much sensation in this community from the prominence of, what the Court does not hesitate to pronounce, the swindle. It deserves to secure wide publicity, if publication of any fact whatever will serve to bring the warning needed. There is one class always to be found in such affairs who never will be warned. Even the blow that wipes them out of existence to-day will have no effect to deter some similar adventurer to-morrow from entering upon a new scheme of "*Something for Nothing*," a penniless game of pitch with gulled stockholders, in which the last have not the least chance of winning. This class of men are beyond reform or rebuke. But the warning should come to the honest citizens who really put money into such schemes. It should plead them to look a little more closely at the workings of the machine. Men of prudence and scrupulous tact, who hold every bank-note up to the light to detect a counterfeit, who will not buy an acre of land without a careful challenge of flaws of title, who bring their butcher and baker and other tradesmen to strict account in their daily transactions, are constantly investing their money in these specious stock schemes, where the outlay is thenceforth unwatched, and the whole enterprise left to the hands of a manager accountable to no one. It would be interesting to go through this community, and learn, privately, from each of our present generation of business men, how much they have lost in stock schemes in the past ten years, and to review the glowing phantasms that have cost them so much. We fear, however, that, even were this whole story told, it would but slightly deter the formation of a precisely similar list in the next ten years. It is so charming, this "*Something for Nothing*," that it will be done over and over again. Only change the names in Judge Lawrence's decision, and his ringing utterances would apply to very many exploded stock schemes here, save, perhaps, in the success in *finesse* of the chief party in this particular instance.

Another branch of the warning rebukes the too common error of citizens of high standing, large business, and irreproachable integrity in too easily lending their names and credit to designing conspirators, who could make but very little or no headway without them. This is all that Judge Lawrence attaches to the name and reputation of David A. Gage, in the case of the Great Western Telegraph Company. It would be difficult to persuade our community to believe that he shared in this confusion deliberately undertaken for the sake of plunder, and our citizens are well prepared for his complete exoneration in this decision of Judge Lawrence. His too easy kindness has been the fault of other prominent citizens before him, and yet a few experiences made public of this kind should make every man of business cautious in allowing his high reputation to be loaned out like an overcoat to cover poverty or plunder.—*Chicago Tribune.*

FOREIGN TELEGRAPHIC ITEMS

THE TELEGRAPH TREATY BETWEEN GERMANY AND AUSTRO-HUNGARY.

The telegraph treaty between Germany and Austria comes into operation on the 1st of January next, remaining in force for an indefinite period, but it may be dissolved at any time by either party after twelve months' notice of such intention shall have been given. The following are the principal stipulations: in the mutual traffic between any of the telegraph stations in the Austro-Hungarian Monarchy and those of any part of the German Empire the charge for a single rate of twenty words is fixed at one Austrian florin or 20 groschens, whilst telegrams from one frontier station to another on the opposite side pay only half of the above charge. For this purpose the territory on both sides of the boundary line is divided into squares, in such a manner that every degree of latitude is divided into five, and each degree of longitude into three equal parts, and at the points where these lines cross are drawn meridians and parallels, by which fifteen squares are formed; and telegrams from any station to another in the same square are charged at the reduced rate. With regard to messages to more distant countries and only passing through the territory of either of the high contracting parties, the charges settled, or which may at any future time be settled in international treaties, are to be in force; but a special exception is made for telegrams between the Austrian dominions and Holland, passing through Germany, such telegrams to be subject only to the charge of 80 kreutzers or 12 groschens. On the other hand, Austria is to have the right to charge on such messages a terminal tax of 40 kreutzers or 8 groschens, by which, including the terminal tax agreed to by special convention with the Netherlands, the total expense of such a telegram comes to 1fl. 20 kreutzers, or 24 groschens. The money paid for messages between Germany and Austro-Hungary belongs to the government of the country where it is raised, but the rates paid for messages in transit must be accounted for according to the stipulations of the International Treaty; though in all messages to and from the Netherlands the charge is to be made without reference to the number of words contained in each telegram, but simply by the number of messages, at the average rate of 60 kreutzers, or 12 groschens. With regard to the terminal charges for telegraphic correspondence between the Austrian monarchy and the kingdom of the Netherlands, the accounts will be made up and balanced by the respective administrations of the telegraphic departments of those states. Till the charges stipulated in the International Treaty for the territory of the Telegraph Union are superseded by special rates for Austro-Hungary and the Empire of Germany, the provisions of the International Treaty concluded at Baden-Baden on October 25, 1868, remain in force as binding on all parties concerned.

THE Trans-Caucasus Provinces being only connected with the telegraph system of Russia in Europe by the single route of Tiflis and Stavropol, and, moreover, the communication being frequently interrupted, orders have been given by the Russian Government to lay down a second line of telegraph to those distant parts through Astrachan and Kisliar.

POST OFFICE TELEGRAPHS.—Statement showing the total number of messages forwarded from Postal Telegraph Stations in the United Kingdom during the week ended the 14th September, 1872, and during the corresponding week of 1871. Week ended September 14, 1872, total number of messages, 327,202; week ended Ssptember 16, 1871, total number of messages, 266,946; increase in the week of 1872 on that of 1871, 60,256.

POST OFFICE TELEGRAPHS.—Statement showing the total number of messages forwarded from Postal Telegraph Stations in the United Kingdom during the week ended the 21st September, 1872, and during the corresponding week of 1871. Week ended September 21, 1872; total number of messages, 321,478; week ended September 23, 1871, total number of messages, 256,456; increase in the week of 1872 on that of 1871, 65,022.

THE Government of Brazil has granted to Baron Mana a concession for a telegraph cable between Brazil and the Portuguese coast.

WHEATSTONE'S PATENT MAGNETIC COUNTER.—This instrument has been devised for the purpose of counting and registering the periodical motions of any machine, whether rotary or oscillating. It may be applied either near or at any distance from the machine whose motions are to be registered. It is less cumbrous than mechanical registers, and cannot be tampered with by persons in charge of the machine.

No Voltaic battery is employed, the electric currents being produced by a small piece of iron attached to the moving part of the machine, working before the poles of a magnet; it therefore requires no more attention than an ordinary piece of mechanism.

Among the purposes to which this register has been applied are the following:

To count the number of impressions produced by any printing machine.

To count the number of revolutions of a screw or paddle shaft of a steamship.

To count the number of visitors who enter a theatre or any public place.

By means of these instruments, also, the rate of working of any number of machines may be seen and compared by the overseer in any distant apartment, without the necessity of visiting the machines themselves.

CORRESPONDENCE.

A GOOD SUGGESTION.

To the Editor of the Journal of the Telegraph:

Would it not facilitate business, if superintendents—especially railroad superintendents of telegraph—would REQUIRE all managers to give notice twice a month that they *have copied* changes in tariff from JOURNAL into tariff books? An operator taking a new office would not then start a message to a point at which the office had been closed six months, or check for other lines after an office had "a square." He would also know whether there was an office at Jonestown, or any other point, without asking all his neighbors. It would be a good time to commence with the new books.

To the Editor of the Journal of the Telegraph:

A party telegraphed through my office the other day, and requested me to make a duplicate of his message, and insert at bottom of message that "This is a correct copy of telegram sent by me Oct. ——, 1872," and for me to sign my name as operator. Answer me in your next issue if I must comply with such a request. BRANCH OFFICE.

Rule 92 reads as follows: "*All Managers and other employés are strictly prohibited from furnishing copies of original messages, or from certifying to the correctness of any message or any copy thereof, whether sent or received.*"

An operator down South, sends the following:—

"The greatest annoyance we experience in these parts is the figure "9," used upon every occasion and for a thousand trifles. I begin to look upon the figure "9" as a great fraud, and an imposition upon an innocent calling. If these "young bucks" down here call an office on some way line half a dozen times without being answered, they think they are imposed upon, and immediately come to the main wire and by singing out "dash two dots and a dash," stop press, signals, cables, or anything else and say, "answer us on No —." I try to keep still when they do that, but sometimes I let out on 'em unknowingly. They interrupt and delay important business by saying "9," and then say something which, if said the next day, would answer the same purpose to themselves and the Company. For the sake of suffering humanity tell us and the balance of the ignorant craft, the literal meaning of "9," and if you can in any way aid in stopping the abuse of the signal, you will confer a favor upon the craft."

Our indignant and inquiring correspondent is informed that the signal "9" means "give way for testing wires." If the signal is improperly used it is his duty to inform the Superintendent of the fact, and he will see that the abuse is corrected.

SALEM makes the following inquiry: If we receive a message from Boston, collect, and are obliged to forward it to another city, how do we check?

Answer.—If you receive a collect message you deliver it to the person addressed, collect the tolls upon it and charge yourself with the amount. If the party then desires it to be forwarded to another point, treat it as you would any message offered for transmission.

W. H.—You apparently had no discretion in the matter. It was your duty to deliver the message. If any person was at fault it was the one who forwarded it.

C. A. W.—Your proposed modification of the Callaud battery is substantially a return to the Daniells battery. We do not find any practical difficulty arising from the cause you mention. The Callaud battery can be moved without causing a mixture of the sulphate of copper with the sulphate of zinc; but supposing you could not do so, we do not see that it would be of any material disadvantage, since there is no necessity for moving them with much frequency. If the zinc is carefully removed there need be no disturbance of the solutions.

G. F. P.—We think the best course in such a case would be to send the message back for explanation.

ELECTRICITY AND LIFE, IN THE LIGHT OF RECENT RESEARCHES.

M. Papillion contributes to the *Revue des Deux Mondes*, a paper on this subject, from which we cull the following facts:—

The controversy between Galvani and Volta is well known. Science has proved, on one hand, that there is an electricity proper to animals, and, on the other, that electricity produced from an external source has an influence on animals.

The best evidence of animal electricity is met with in certain fishes—the torpedo, the gymnotus, the silurus, the ray, &c. The electric fluid is subject to the animal's will, and is similar to machine electricity in its effects. It gives shocks and sparks when of sufficient tension. The source consists of a series of small discs of a particular substance, separated from each other by partitions of laminated tissue, and with fine nerves distributed over their surface. It is generally situated in the region of the head, but is sometimes near the tail.

All animals are electrical, however. An electricity of the nerves and muscles (independent of their characteristic action) has been proved by Nobili, Matteucci, and Du Bois Raymond. If a frog's muscle be prepared, and touched at two different points, by the two ends of a nerve filament of the animal, it contracts under influence of a current. If a muscle, taken from an animal recently killed, be cut across the fibres, and the wires of a sensitive galvanoscope be connected, one to the natural surface the other to the cut surface, the passage of a current is indicated. A stronger current may be got by superposing several sections in form of a pile; the positive pole in which is the natural surface of one of the terminal sections; the negative pole the sectional surface of the other.

Currents are produced in other parts of the system—e.g., between the external and internal parts of the skin, in the blood, in the secretory organs. M. Becquerel has demonstrated the fact of electro-capillary action. Two different solutions, conductors of electricity, separated from each other by a membrane or a capillary space, constitute an electro-chemical circuit, and in the animal system there are numerous couples of such a character. The arterial blood and the venous blood form a couple, the electromotive force of which is equal to 0·57, that of a nitric acid couple being 100. This field, little investigated as yet, is likely to furnish valuable aid in interpretation of physiological phenomena. Plants also develope electricity. M. Becquerel has shown the existence of currents in fruits, stems, branches, and leaves. He took the stem of a young poplar, connected a platinum wire with the pith, and another with the bark, and both of these wires with a galvanoscope, which then indicated a current. M. Buff has proved the existence of currents from the root towards the leaves.

The fact of animal and plant electricity being therefore established, let us next see what are the effects, on living organisms of electricity from without.

The atmosphere contains a varying amount of positive electricity; the earth is always charged with negative electricity. It is doubtful how the electricity is developed; some physicists think it arises from vegetation and evaporation. M. Becquerel considers the sun the chief source of atmospheric electricity; which it emits, as it does light. However caused, it is only when accumulated, that it produces marked effects on life. Persons struck by lightning are variously affected. Sometimes they are struck rigid on the spot, sitting or standing; sometimes they are thrown to a distance. The lightning at times destroys the clothes, sparing the body; at other times the reverse happens. In the latter case the heart is often rent, and the bones are broken, while at other times the organs remain entire. Sometimes a softening and flaccidity is produced in the members, at other times there is contraction and rigidity. The body often decomposes rapidly, and often resists decomposition for a long time. Where death has not been caused, various sorts of maladies often appear, which may be temporary, or may be irremediable. Not to mention burns, eruptions on the skin, loss of hair, &c., the person sometimes becomes paralyzed, or deaf, or dumb, or blind, or imbecile. In short, electricity affects all the functions of the nervous system.

The action of electric fishes is often formidable. Humboldt, on one occasion, having put both his feet on a gymnotus, received a shock so violent that his limbs ached for the rest of the day. The streams containing such fishes become unfordable for mules or horses. Mules have been known to die from the discharges. To catch the fish, the Indians drive wild horses into the stream; these the fish attack, and, after their discharge, are found in a weakened state and easily harpooned. The natives use the gymnotus in treatment of paralysis. Faraday compared the shock of a gymnotus which he examined, to a batterie of 15 jars. On touching with the hand a live torpedo, a shock is felt, which is strong in proportion to the surface of contact. Electricity from an artificial source—a machine or an induction apparatus—affects the animal tissues variously. Dutrochet, in his researches on Endosmose (a kind of action which takes place extensively in animals and plants), put a tube closed at the lower part by a membrane, and containing water mixed with gum, in a vessel of pure water. The surface of the gummed water gradually rose, owing to the entrance of pure water across the membrane. Some of the gummed water also passed into the pure. It was proved, however, that in such cases, the current from the less dense to the more dense of the two liquids was more rapid than the opposite current. Dutrochet further observed that if the positive pole of a pile was placed in the pure water, and the negative in the gummed water, the endosmotic action was increased. MM. Onimus and Legros have found that by reversing the position of the poles, the surface of the liquid in the tube descends, instead of rising. Thus electricity reverses the ordinary laws of endosmose.

It variously affects also other physico-chemical actions in the system. It decomposes salts, and coagulates albuminoid matters of the blood in the tissues, just as in the vessels of a laboratory. The nutritive processes are affected by it. Continuous ascending currents accelerate the motions connected with assimilation. Animals electrified under certain conditions produce an increased quantity of urine and carbonic acid, indicating greater energy in the vital functions. Young animals subjected to electric currents grow larger and more rapidly than in ordinary circumstances.

JOURNAL OF THE TELEGRAPH,

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, OCTOBER 15, 1872.

FREE BUSINESS OF THE WESTERN UNION TELEGRAPH COMPANY.

The rules of the Company provide that official and private messages sent free by the employés of the Company must be limited to matters of an urgent nature, and that the mail must be used in all cases where it will subserve the purpose desired. These rules, however, do not seem to be properly observed. During the past year the amount of social free business done by the employés of the company amounted to over $70,000. This item, however, is insignificant in amount when compared to that covered by the service messages transmitted by the employés. The eminently wise precautionary rule which requires the limitation of official messages to matters of an urgent nature seems to be almost wholly disregarded by all classes of employés. The pressure upon the wires produced by the great quantity of this class of messages proves not unfrequently a source of great embarrassment and sometimes of delay to the revenue producing business.

A case in point, and one which suggested these remarks, occurred recently upon one of the busiest and most important circuits in the country. The business of the circuit was unusually large and was rapidly accumulating, when a lengthy message, or rather a letter, regarding a check error amounting to fifty cents, was sent over the wire. The value of the time occupied by the transmission of this message was worth to the Company many times the amount involved in the error. It is of the utmost importance that all check errors should be promptly corrected, but it is not right that the valuable time of important circuits should be occupied for this purpose. The message referred to would have accomplished its desired object just as effectually had it been sent by mail or had it been detained until the business of the day had been finished.

With reference to the personal messages of employés there is no desire on the part of the Company to restrict the transmission of those of an urgent character. It is only desired that the employés shall restrict themselves to such matters as cannot await the delivery by mail. A great many personal and social messages transmitted for the employés of the Company seem to be wholly unnecessary, and such as would not be sent if payment of tolls were exacted.

If each employé of the Company will reflect that he constitutes but one out of an army of ten thousand in the service, he will perceive how the comparatively insignificant amount of his own free service becomes swollen into an enormous volume when multiplied by the whole number of persons employed. Let each employé therefore of every grade, from the highest to the lowest, consider, when he writes a message, whether the purpose cannot be accomplished as well if sent by mail as if sent over the wires, and if so, then by all means use the mail. If the mail will not serve his purpose, then let him consider whether the message cannot be sent at night; and if so let him write it upon a red blank and have it transmitted at a time when the wires are not occupied with important full-rate business. If the matter which he wishes to send is of such pressing importance as to require the best facilities of the Company at the most important hours of the day, then let him write it upon a full-rate blank in as condensed a form as he would write it if he was to pay in cash the regular full-rate for its transmission.

If every employé of the Company would reflect that a free message costs just as much to send as a paid message, and that the average cost of every message sent by the Company is two-thirds of the tolls charged, we are quite sure that the annual working expenses would be materially reduced by the diminution in personal and service messages.

The two classes of messages sent by the officers or employés of the Company may be designated by the word *Immediate*, written upon those requiring prompt transmission and by the word *Red* upon those which can await the convenience of the service.

PLEASANTLY REMEMBERED.—A very pleasant surprise was made upon Mr. E. W. Bradford and his wife at their residence on Austin street, Worcester, Mass., Thursday evening. A large number of the many friends Mr. Bradford has made as manager of the Western Union Telegraph office and in social life, gathered, with gifts and congratulations, to celebrate the tenth anniversary of his wedding day. During the pleasure of the evening Mr. Albert P. Hopson, in behalf of the party, presented Mr. and Mrs. Bradford with a costly silver set, with some fine table linen, upon which its several elegant pieces may do future service.

ATTENTION is called to the advertisement of Mr. Eugene F. Phillips, of Providence, R. I., manufacturer of telegraph office wire of all descriptions, which appears in this issue. We are assured that the wire furnished by Mr. Phillips is of a superior quality, and that his terms are very reasonable.

THE Captain-General of Porto Rico has dismissed Mr. Morris, the cable electrician, from the service, because he is also editor of the *Boletin*, an organ of the ultras, and because he wrote against the radicals and criticised the Captain-General.

RETIREMENT OF MR. W. H. ABEL, AUDITOR WESTERN UNION TELEGRAPH CO.

In consequence of continued ill health, Mr. W. H. Abel, Auditor of the Western Union Telegraph Company, has retired from the active supervision of his department.

This course has been rendered necessary from the fact that his attendant physicians advise him in the strongest manner to pass at least a year in the South of Europe and in Africa. He accordingly sails in the steamer Adriaticon Saturday, 19th inst., for Liverpool and from thence by earliest conveyance to Egypt.

Mr. Abel has, for a number of years past, been suffering from a bronchial complaint, which latterly has assumed an acute form; and the respite from his engrossing labors, which, heretofore, he has felt unable to take, is now absolutely forced upon him.

We trust that Mr. Abel will be so benefitted by this trip, that he will be able upon his return, to again assume, with his characteristic vigor and energy, the duties of his position.

RESIGNATION OF MR. TUNIS J. POWELL.—APPOINTMENT OF HIS SUCCESSOR.

Mr. Tunis J. Powell, of the auditors' department, who has been in charge of the Atlantic and the Cuba Cable accounts since the commencement of cable business, resigned his position on the first of the present month.

In the performance of his duties Mr. Powell has given unqualified satisfaction to the company. He leaves with the regret of all who have been immediately associated with him, and with the best wishes of all connected with the service.

He sails with his friend, Mr. Abel, on the 19th, on a pleasure excursion to Europe and to such other parts of the world as occasion and circumstance may induce.

Mr. Powell is succeeded by Mr. George W. Roberts, lately of the bookkeeping department, who, from his antecedents, will doubtless fill the position with honor to himself and profit to the company.

APPOINTMENT OF MR. LEONARD COX AS CASHIER OF NEW YORK OFFICE.

It gives us much pleasure to announce the appointment of Mr. Leonard Cox as Cashier of the New York Office of the Western Union Telegraph Company. The position is one of the most important in the service, requiring just the skill and ability which Mr. Cox is able to bring to it.

Prior to 1865 Mr. Cox was Cashier of the Charleston and Columbia, S. C., offices. Since then he has been Secretary successively to Gen. Marshall Lefferts, President J. H. Wade, and to Vice-Presidents McAlpine, Green, Walker, and Mumford.

Politeness and courtesy are indispensible for an easy path through life, and they are no less necessary for a successful and proper performance of business duties. Prompt and courteous attention to customers is enjoined. Nothing is more annoying to a customer than indolent and apparently indifferent attention. Civility costs nothing and always pleases.

TO OUR correspondent at New London, Ohio, we would say: The columns of the JOURNAL is hardly the place for a communication of the character he favors us with. He had better address the party he complains of direct. If he then fails to receive satisfaction, and there was fraud in the transaction, his best course would be to request the intervention of the Superintendent of the delinquent.

THE ANNUAL MEETING OF THE STOCKHOLDERS OF THE WESTERN UNION TELEGRAPH COMPANY.

ELECTION OF OFFICERS.

The annual meeting of the stockholders of the Western Union Telegraph Company was held on Wednesday, October 9th, at the office of the Company, 145 Broadway, the President, Mr. William Orton, in the chair. The first business transacted was the election of a Board of Directors for the ensuing year. Messrs. George B. Prescott, J. D. Reid, and William Arnoux acted as inspectors of election, and the following gentlemen were unanimously re-elected as Directors for 1872–73; William Orton, James H. Banker, Horace F. Clark, Alonzo B. Cornell, Harrison Durkee, Augustus W. Greenleaf, Edwin D. Morgan, O. H. Palmer, Augustus Schell, John Stewart, E. B. Wesley, Hugh Allan, Nathan A. Baldwin, William D. Bishop, Ezra Cornell, William E. Dodge, Sheppard Gandy, Norvin Green, John A. Griswold, Wilson G. Hunt, George Jones, C. Livingston, E. S. Sanford, Hiram Sibley, Z. G. Simmons, Moses Taylor, Daniel Torrance, George Walker, Stillman Witt. The number of votes cast was 273,116, representing stock amounting to $27,-311,600.

The election being over, William Orton, President of the Company, submitted an able and exhaustive report, exhibiting in detail the operations of the Company for the last fiscal year ending June 30, 1872, from which the following items of interest are extracted: On the 30th of June, 1872, the Company operated 62,032 miles of line with 137,199 miles of wire. All this is operated through 5,237 offices. The increase during the year past was 6,000 miles of line, 16,039 miles of wire, and 631 offices. To perform the labor required for such vast operations the Company has in its employ 8,347 operators, who last year transmitted 12,444,499 messages, being an increase of 1,788,422 over the year preceeding. The gross receipts for the year were $8,457,095 77, the expenses $5,666,863 16, leaving a net profit of $2,-790,232 61, which is an increase over the last year of $819,646 92 in the gross receipts, $562,075 97 in the expenses, and $257,570 95 in the net profit. During the past year the company has introduced one of the most important inventions for the transmission of messages which has been made since the telegraph first went into operation. This is the duplex telegraph invented by J. B. Stearns, by means of which messages can be transmitted in opposite directions on a single wire at the same time. It has come into very general use, and has afforded vastly increased facilities for telegraphing. The present Western Union system dates from the consolidation of the United States, the Southwestern, and the American Companies in 1866, and the net profits during that six years ending June 30, 1872, amount to $17,116,694 23. Of this sum $4,856,879 34 was distributed to the stockholders in dividends, and $1,-898,401 98 disbursed for interest on the Company's bonds. The balance—$10,361,412 91 was expended in the construction of new lines, the erection of additional wires, and the purchase of telegraph property.

The report of the President was accepted, and on motion a suitable number of copies were ordered printed in pamphlet form for distribution among the stockholders. The meeting then adjourned.

On Thursday, October 10, the Board of Directors elected the following gentlemen officers for the ensuing year:

President—William Orton; Vice-Presidents—A. B. Cornell, O. H. Palmer, Augustus Schell, George H. Mumford.

TARIFF BUREAU.

SEMI-MONTHLY CIRCULAR.

EXECUTIVE OFFICE,
WESTERN UNION TELEGRAPH COMPANY,
145 Broadway, New York.
October 15, 1872.

To all Offices on W. U. Lines:

The following changes and additions have been made since the date of the last circular.

GENERAL INFORMATION.

Offices in ILLINOIS and WISCONSIN are hereby instructed to use STATE RATE of FOUR dollars to IDAHO and MONTANA TERRITORIES; and offices in IOWA and MISSOURI to use SQUARE RATE to offices in IDAHO, MONTANA, NEW MEXICO, and SQUARE rate *when given* to offices in UTAH.

Messages addressed to Union Stock Yards, Ill., should not be checked to Chicago. The office at the Stock Yards should be checked direct on all messages addressed to it.

Macon Station, Ala., closed.
Evansville, Ala., "
Marianna, Ark., re-opened.

CUBA CABLE BUSINESS.

The Cable to Aspinwall is now open for business. Tariff, five dollars, gold, for ten words; fifty cents for each additional word, in addition to the present rate to Jamaica, via Cuba Cable.

WILLIAM ORTON, President.

TRANSFER SERVICE.

EXECUTIVE OFFICE,
NEW YORK, Oct. 5, 1872.

On and after Monday, the 21st inst., Mobile, Ala., will be added to the list of money order offices, *specially authorized*. I. C. HENDRICKSON, Transfer Agent. G. H. MUMFORD, Vice-President.

EXECUTIVE OFFICE,
NEW YORK, Oct. 15, 1872.

On and after October 21st, *Dallas* and *Palestine*, *Texas*, will be added to the list of money order offices in D. P. Shepherd's District and Hallville, Texas, to list in W. A. L'Hommedieu's District.

G. H. MUMFORD, Vice-President.

THE following are the awards of premiums to electrical and telegraphic instruments and apparatus at the Cincinnati Industrial Exposition:

Best telegraphic instrument for private use, silver medal to Merchants' Manufacturing and Construction Company, New York City.

Greatest improvements in telegraphy, silver medal to STEARN'S Duplex, entered by Western Union Telegraph Company.

Best burglar alarm telegraph, bronze medal to HOLME'S Burglar Alarm.

Best electric gas lighter, silver medal, Electric Gas Lighting Company, New York City.

Best system railroad signals, silver medal, F. L. Pope & Co., New York City.

BORN.

TRUE.—At Tuckerton, N. J., October 10, 1872, to W. F. True, Manager W. U. T. office, a daughter.

MARRIED.

CASSIDY—GRAY.—At Barry, Ill., September 18, in the Baptist Church, by the Rev. H. L. Stetson, James P. Cassidy, of the Superintendent's office of the Western Union Telegraph Co., at St. Louis, Mo., to Miss Josephine Gray, of Barry, Ill.

COLVIG—DYER.—At Canyonville, Oregon, September 23, 1872, George W. Colvig, Manager W. U. Tel. office, Canyonville, to Miss Mary Dyer, of same place.

CROCKETT—VAIL.—On Thursday Oct. 3, 1872. at the residence of A. S. McCormick, R. W. Crockett, Agent and Operator T. W. and W. Ry., Rockfield, Ind., to Miss Delphine Vail, of Delphi.

DIED.

BERRY.—At New Orleans, La., October 6, of diptheria, Daniel Trant Berry, of Racine, Wis., after a residence at that place, in the employ of the Western Union Company, of one month.

Mr. Berry was widely known among telegraphers, having been many years in the profession. He was an honorable man, one of the most genial of companions, and a steadfast friend.

HIGDON.—At Kit Karson, Col., Wednesday, September 20, suddenly, of heart disease, Mr. George E. Higdon, formerly of Indiana, an operator of the Kansas Pacific Railway Telegraph.

His remains were sent East to his friends.

OLIVER.—At Hugo, Col., September 30, burned to death, accidentally, Mr. G. D. Oliver, formerly an operator on the Denver and Rio Grande R. R. Telegraph.

RANDALL.—At Ann Arbor, Mich., September 13, after four months' illness of inflammation of the bowels, Fred. A. Randall, aged twenty-one years and six months.

OBITUARY.

FRED. A. RANDALL.

The deceased was a member of the Telegraphers' Mutual Life Insurance Association. He learned the telegraphic art at Ann Arbor, Michigan, six years ago, in the office of the Western Union Telegraph Company. He was first employed on the telegraph lines of the Michigan Central Railroad as an extra operator, which position he filled to the satisfaction of his employers for three years. He then entered the Western Union Telegraph Office at Jackson, Michigan, where he remained one year, when he was offered and accepted a situation with the same Company under the management of Mr. Doolittle, at Lafayette, Indiana.

After serving in that office one year, he came to Chicago, Ill., and accepted a situation with the same Company on the night force of the Chicago office. His worth was soon discovered, as he was an operator of more than ordinary ability, not only as a manipulator of the key, but as an electrician, and he was promoted to a position on the day force, where he worked some of the best wires in the office. In the nine months that he was in actual service here, he made friends of all with whom he was brought in contact.

As a companion and brother operator he was all that could be desired, his conversation showing at all times his genial, warm-hearted nature; no unkind or insinuating remark was ever heard from his lips. As a son he was the personification of dutiful affections; as a brother his devotion was unbounded, his love of home and domestic society causing his early death to be the more keenly felt. May we who survive him cherish his many virtues and profit by his manly example.

OFFICERS OF THE WESTERN UNION TELEGRAPH COMPANY.

JOURNAL OF THE TELEGRAPH.

VOL. V. NO. 23. NEW YORK, NOVEMBER 1, 1872. WHOLE NO. 120.

WHEATSTONE AUTOMATIC TELEGRAPH.

BY R. S. CULLY.

The advantages of machine over hand labor are as apparent in telegraphy as in any other mechanical act, even without regarding speed, for signals mechanically sent will always be better formed, and more legible, than those sent by the key. But we are able to show, from experience, that besides assuring better signals, a greatly enhanced speed can be attained by the automatic system.

My intention, in this paper, is to speak only of those automatic systems of which I have personal experimental knowledge, and I am in consequence obliged to pass over more than one of great merit; among them, that bearing the name of our worthy President.

The system of Alexander Bain was the first that was actually worked in this country, and the method of signalling by means of perforated paper, which is, I think, employed in all systems, was introduced by him. It was tried between London and Birmingham, or Birmingham and Gloucester, in about the year 1850, and I myself used it between Manchester and Liverpool in 1852. It failed, partly because the insulation of the wire was too variable to allow of rapid signalling except in fine weather, but mainly because we had no good punching apparatus. I revived it some three years since between London and Southampton, attaining a rate of 60 words per minute, and should have continued the trial had it not been that such an arrangement had been concluded with Sir Charles Wheatestone as rendered it unnecessary to improve a method radically inferior.

Bain perforated the paper ribbon in such a manner that the punctures represented the Morse signals themselves, but, as it were, magnified. A wire brush rested on the ribbon, and made contact with a metal wheel through the holes in the paper. This plan has several objections; dust or fibres of the paper are apt to interfere with the contacts, and what is more important, the edges of the perforations act upon the brush in a manner which prevents it touching the metal wheel over a considerable portion of the space allowed for contact. Better results were obtained by lengthening the perforations in the paper, and running the machine proportionately faster. The system employed by the Postal Telegraph Department is Wheatstone's, in which the contacts are made between levers and studs, the paper being used only to regulate the movement of these contact pieces. This arrangement gives much more uniform and trustworthy contacts than can be obtained between a brush or spring and a revolving wheel, and affords great facilities for the production of the compensating currents, which are required at high speeds. The principle of the apparatus is that the armature of the electro-magnet, which causes the printing disc to touch the paper, shall not have a tendency to leave the paper when the marking current ceases, but shall remain always in the same position in which it is left by the last current. The machine is arranged to send a series of reversals or alternate + and — currents at definite and regular intervals, and the function of the perforated ribbon is to decide whether these currents of either sign shall or shall not pass out to the line. An ebonite rocking beam (R, *Fig.* 1), moved by wheel-work, carries three pins, that on the left hand is connected to "line," that on the right hand to "earth;" the centre pin is insulated, and serves to connect the curved lever (B, *Fig.* 1) with one or other of the battery levers (Z, C), according to the positon of the rocking beam. Under the beam lie the two levers (A,B). These levers are pivoted independently, but are in electrical connection through the spiral springs (H, H1) attached to them, and through the frame of the instrument. On the ends of these levers (A,B) are pivoted the vertical needles (V,V1). The one (V) regulates production of the marking, the other (V1) that of the reverse or spacing current. These levers are not *fixed* to any of the moving parts of the apparatus, but are firmly pressed upwards by the spiral springs (H, H1, Fig. 1) so as to follow the movements of the rocking beam, and remain in contact with the pins inserted into this beam so long as their upward movements are unchecked. The needles attached to these levers determine whether line contact should be made or broken at the moment battery-contact is made. Their rise alternately until they touch the paper ribbon; if there be a hole opposite their points, they pass through it and the contact is undisturbed; but should there be no hole, their motion and that

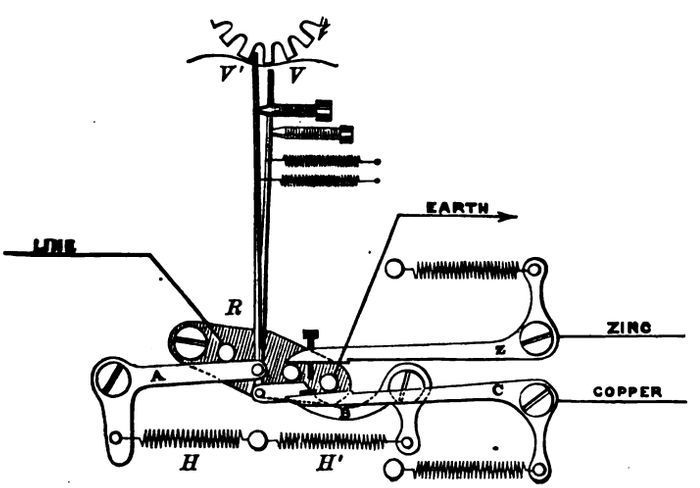

Fig. 1.

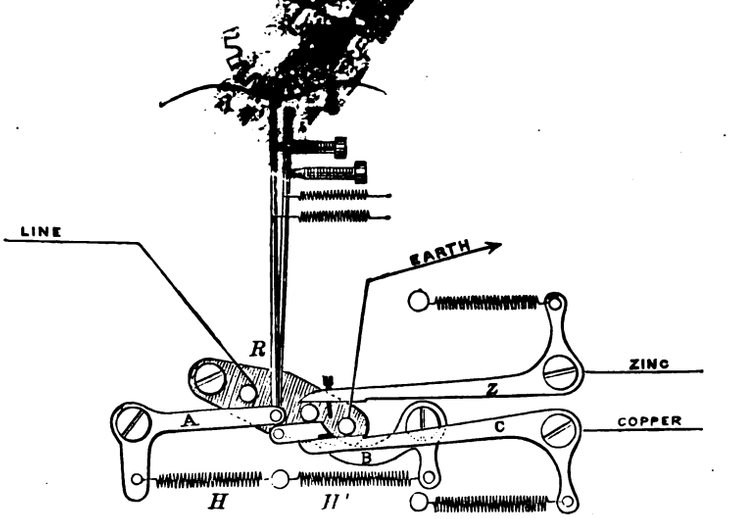

Fig. 2.

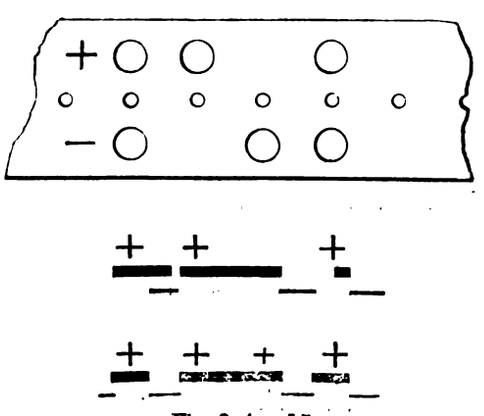
of the lever is stopped, and the pin on the rocking beam continuing to rise, contact is broken between it and the lever.

Fig. 1, shows the apparatus in a position for sending a negative current. The levers Z and C are the poles of the battery. The lower lever C touches the right hand pin on the rocking beam, and as this pin is in connection with the earth, the copper pole is in connection with the earth also. The upper lever Z, which is in connection with the zinc pole of the battery, rests on the centre pin of the beam, and is in connection with the line through the lever B, the spiral springs H, H1, and the frame of the instrument, the lever A, and the left hand pin; and thus a *negative* current has been sent to line.

Fig. 2 shows the position where the current is broken. The rising of the lever A is prevented by the paper, the vertical needle V1, attached to it, not meeting with a hole in the ribbon. Here the contact between the lever A andthe left hand pin is broken, and no current passes on to the line.

When the speed of transmission is increased beyond a rate which varies with the length of the circuit, embarrassment arises which is partly due to in-



Digitized by Google

duction when the potential of the line wire varies with the interval between the currents, and partly to what may be called the "inertia" of the electro magnet of the receiving apparatus, the time occupied by the magnetising and demagnetising the iron, varying also with the interval between the currents, and probably even in a comparatively short suspended wire, not more than 70 words per minute could be attained under Bain's method, where the currents are sent precisely in the same manner as by an ordinary single current key.

With reversals, speed is increased, but is still considerably lower than the maximum to be attained on a given line. It is well known that a succession of equal currents of opposite signs, at equal intervals, will give perfectly distinct *dots* at a very much higher speed than the *dots* and *dashes* of an alphabet can be produced.

Wheatstone's apparatus produces the Morse signs by currents of equal duration; or, in other words, by a succession of *dots;* but as the intervals between the currents are necessarily unequal the alphabet is more slowly produced than a series of equidistant *dots*. The speed of a succession of letters (an alphabet) depends also on the distance between the letters, the *greater* the interval the *slower* the speed, because an additional element of variation in the electrical condition of the wire and the magnetism of the receiver is thus introduced. Speed is generally limited more by defects in the formation of the letter than by the loss of dots, or running together of marks, and the defects are greatest where there is the greatest irregularity in the intervals between currents, as for instances, in F — — — — R — — — It is necessary, then, to apply a system of compensating currents to maintain as great a uniformity as possible in the condition of the wire and electro-magnet.

This was effected in the first instance by bridging over the break in the circuit which occurs when the pin is stopped by the paper, by resistance coils, so that a weak current was sent in the interval of break, the strength of which currents was regulated by varying the resistance. This system was further improved upon by an alteration of the transmitter by which the compensation was more accurately applied, and it is upon this principle the apparatus is at present constructed, although experiments in a different direction are in progress which may bring about a further improvement in the system.

Figs. 3, 4 *and* 5.

Fig. 3 is intended to represent a piece of the perforated ribbon, the perforations which regulate the contact making portion of the transmitting apparatus are represented by the larger circles, while the centre row of holes is represented by the smaller circles; by this row of holes the paper is carried forward in the transmitter.

The slip is perforated for the letter R of the Morse alphabet; this letter has been selected as being one which is always much deformed, and which shows the effect of a dot preceding and following a dash. The upper row of holes is that which allows a positive or marking current to be sent when the vertical pin V (Figs. 1 and 2) of the transmitter passes through one of them. The lower row of holes allows a negative current to be sent in the same way when the vertical pin V1 (Figs. 1 and 2) of the transmitter rises through one of them.

Fig. 4 represents the letter R of the Morse alphabet, as received at high speed on a line where the original system of intermittent currents is used. It will be seen that in the case of the dot before the dash, a +, then a —, and finally a second +, that is two positive, and one negative current are sent to form the dot and to commence the dash; that is, twice as much positive as negative current, and the dot is consequently much elongated, and has a tendency to run into the dash. In the case in which the dot follows the dash, it will be seen that the case is exactly the reverse of the former, and for the finish of the dash a — current is sent followed by a +, and finally by a second — current, the last two to form the dot; that is two — and one + current are sent, so that in this case the line is charged negatively in excess; consequently the space between the dash and dot is considerably increased, and the dot much shortened or lost altogether.

Fig. 5 shows the letter R as received where compensating currents are used, and is perfect with respect to the length of the marks and the spaces between them. The compensating currents are represented by the smaller signs. It will be seen, that before the commencement of the dot the line is charged negatively, instead of being left clear, as in the original system, and prevents the elongation of the dot before the dash, as already explained.

In the case of the dot following a dash, it will be seen that a positive compensating current is sent before the terminating current for the dash, so that the line is not too much negatively charged, as where no compensating currents are used, and the elongation of the space separating the dash from the dot, as well as the diminished size of the dot itself, is prevented. (Fig. 5.)

The principle of compensation is, I am aware, not new; but I think no practical way of applying it has before been proposed.

In a circuit composed partly of over-ground wires, and partly of buried or submarine wires (and all our circuits contain a considerable proportion of buried wire), the position of the underground work or cable will effect the speed at which the two stations can receive from each other. If the buried portion or portions be symmetrically placed with respect to the two stations, as when the land lines at each end of a cable are of equal length and resistance, the two stations will be able to read each other equally well; but if the land lines on one side be much longer than at the other, the rate at which the station at the end of the shorter land line will be able to receive, will be *less* than that at which the station situated at the end of the longer land line can receive from the other. This difference of speed is sometimes very considerable, and the difference is the greater as the lengths and resistances of the land lines on each side of the cable are the more different.

The London and Amsterdam circuit is composed of, first a suspended wire of 130 miles, then a cable of 120; lastly, on the Dutch side, a suspended wire of 20 miles.

Here it was found that the relative speeds of signalling were as 9 to 6, the higher speed being Amsterdam to London. The rate to Amsterdam was increased by decreasing the resistance of the batteries; and still further by the insertion of a high resistance (as much even as 5,000 ohms) at Amsterdam (in the receiving circuit only) to delay the discharge of the cable.

But in the case of the London Dublin circuit, where the land lines were 266 and 10 miles respectively, and the cable 66, in all 342 miles, the addition of resistance at Dublin in the receiving circuit has no appreciable effect, because the length of land line on this side is too great to permit the cable to be sufficiently charged. Here the speeds are 40 and 80 respectively. In fact, the speed to Cork from London is 38 words, or nearly as high as London to Dublin, though the distance is greater, the English line being 298, cable 62, and Irish line 124 miles, or in all 484 miles. Here the resistance per mile of the wire is less, the wire being of a larger guage; but the more central position of the cable has a considerable effect. Moreover, the resistance of the English line is equal to only 149 miles of the Dublin line, so that the potential of the English end of this cable can be raised above the corresponding end of the Holyhead cable. The apparatus, as at present made, can be arranged either to send what are technically called "permanent" currents, or to represent an ordinary double current key, or, 2ndly, to send short initial and final currents separated by an interval of insulation, called the "intermittent" system, or, 3rdly, a strong initial and final current, each followed by weaker currents of the same sign, the strength of which can be regulated with great exactness by the amount of resistance which is placed in the battery circuit. This is called the "compensated" system.

To practice the system of working is this: If the weather be dry, and the insulation high, the "intermittent," or perhaps the "compensated" system with a very high resistance, giving a very weak compensation current, is used. When there is contact, the "permanent" system or the "compensated" with a low resistance. This is to keep out the stray current on the same principle as the double current key. In the case of contact it is sometimes found serviceable to add resistance at the receiving end of the circuit, increasing the battery power; this is simply to lessen the tendency to receive the leakages from the adjoining wires.

It has been already shown how resistance is used at the receiving end of the circuit where there are submarine cables. It is used on ordinary land lines for a similar purpose, that of balancing the position of buried wires. It is found that on *east* and *west* wires the speed is decreased about noon. The cause is not clear, bnt it probably is due to the ordinapy diurnal variation in earth currents. There may also be something due to the increased resistance of the wires from the increased temperature. In all cases speed is increased by inserting a shunted condenser at the receiving end.

There is also a very noticeable amount of embarrassment due apparently to the magnetic inertia of the electro-magnet of the receiver.

On short circuits it begins to be felt with "permanent" currents at 70 words; with "intermittent" at an intermediate speed varying with the strength and duration of the compensation current. To overcome this defect we have been for some time engaged in experiments for the purpose of dispensing with the electro-magnet, adopting the well-known principles of a light moveable helix and a large fixed magnet, or a helix within a helix. It may be interesting to state the actual speed attained in practice with the Wheatstone apparatus.

To Aberdeen --- ---	60 words per minute.	
" Sunderland --- ---	90 "	"
" Manchester ---	120 "	"
" Liverpool ---		
" Cardiff -- ---		

In some cases as many as four intermediate stations are introduced on the circuits devoted to the press, on which 1,000 words are sent simultaneously to each station in 20 minutes with regularity. For news-work the ribbons are punched in duplicate, or even in triplicate, and the same ribbon is used for several sets of stations in succession. Indeed, were it not for the automatic system, it would be impossible for the Post Office to convey the large amount of matter handed in by the Press Associations.

F. C. WEBB ON AN ELECTRICAL EXPERIMENT WITH AN INSULATED ROOM.

The object of the author's experiments was to show that the ordinary theory of the action of the Electrical Machine is incorrect. Some years ago the author endeavoured to prove by reasoning that the ordinary explanations given of the discharge of a charged conductor by communication with the ground was erroneous; and suggested an experiment with an insulated room as a means of proving the fallacy of these ordinary explanations of discharge, &c. The extracted results are best given in the author's own words.

It is generally stated in books on electricity, that when an electrical machine has its rubber to earth, on the action of the machine the prime conductor becomes charged positively and the equal quantity of negative electricity which is generated is lost in the earth, and that when the prime conductor is then placed in contact with the earth, its discharge is merely the consequence of its sharing the electricity with the earth, the proportion remaining on the conductor being, in virtue of the almost infinite size of the earth as compared with the conductor, almost infinite small, and consequently quite inappreciable. When, therefore, the ordinary experiment of charging the prime conductor is performed in an insulated room, according to the theories which I deny, the negative electricity being unable to share itself with the earth, some differences in the effects produced should be attained. The negative electricity, for instance, if it tends to flow to the earth, should influence an electrometer placed in contact, and exterior to the room. Again, if the room is connected to the earth during the charging of the prime conductor and is afterwards insulated, the prime conductor, if touched to the room, ought not to be discharged, since it can only share its electricity with the room instead of with the almost indefinitely large surface of the earth. Now, I argue, that when electricity is produced, at any rate by artificial means, the negative and positive are not only always produced in equal quantities, but remain each as much in abeyance as the other, and that complete discharge always consists in the recombination of equal quantities of opposite electricity. Thus when a conductor is charged, say, positively from a plate-machine having the rubber connected to the earth, the negative electricity has no tendency to flow to and distribute itself equally over the earth, but distributes itself principally on the nearest conducting surfaces to the positively charged surface; and when the surface to which the negative pole is attached entirely bounds the dielectric which separates it from the positively charged surface, the negative electricity is entirely distributed on that surface, none flowing to any other part of the earth. When these are joined by a conductor, discharge occurs through the recombination of the exactly equal quantities of electricity previously produced.

For carrying out the experiments a room was constructed about 8 feet by 9 and about 8 feet high. The floor was of wood, and the sides of wooden framework, covered with calico, and with pieces of tinfoil pasted about it, to make it a good conductor. It had a door and two windows of wire gauze. A small table was placed in it, and a frictional electrical machine was placed on this. The room was suspended by four double parts of half-inch-round gutta-percha band to a wooden frame, the floor being about four feet from the ground. The gutta-percha was covered with paraffin, and the whole room was tested for insulation with a delicate astatic Thomson reflecting-galvanometer, and gave no perceptible loss. A Peltier electrometer was placed on the ground outside, and a wire from the brass knob of this was connected to the gauze of the window. The table was connected with the tinfoil that was pasted about the surfaces of the room, so that when the rubber or prime conductor was connected to the table it was in connection with the sides of the room. Thus arranged, the machine acted to all appearance exactly the same as in an uninsulated room. When the rubber was connected to the table, on turning the glass disc, the prime conductor was charged so as to give off sparks the same as when the room was uninsulated; and the conductor was completely discharged when touched to the insulated room. Not the slightest effect was produced on the electrometer, even when sparks were flashing from the prime conductor to the wire gauze of the windows to which the wire from the electrometer was attached. Connecting the room to the earth made no difference. A sphere about a foot in diameter was then charged, when the room was insulated, and then handed out by an insulating handle, when the electrometer immediately diverged to about 50°, showing that the outer surface of the room had become negative. On taking the sphere back into the room, the elcctrometer fell to Zero. It is impossible to reconcile these results with the explanation of the action that takes place in charging and discharging as giving and republished in most works. Take, for instance, the following from Noad's "Student Text Book:"—"Thus, in order to get any developement of electricity, there must be either with the rubber or with the prime conductor, electrical communication with the earth, as the great natural reservoir of electricity." According to the views I have advocated, the accumulation on the prime conductor depends on the resistance of what I have termed the inductive circuit, which, in the case of charging the prime conductor, with the rubber connected to surrounding objects, consists simply of the resistance of the dielectric separating the prime conductor from the surrounding objects, and is therefore the same whether the room is connected to earth or not.

Dr. Ferguson, in his "Electricity," seems to have a tendency to discard the older explanations; but at times his explanations appear to be incomplete, thus he says:—

"We have hitherto taken no notice of the—E, that, for instance, is said to be lost in the ground when glass is charged positively. Now it may be lost, and the—E induced by the glass on surrounding conductors may be new—E induced by it. But it is also possible nay, even probable, that this—E is none other than the—E said to be lost. If this be the case, the ground acts as much on the glass as the glass on the ground; and the action is precisely the same as in a galvanic circuit, when the polarisation proceeds in opposite ways in two opposite directions, the action of the one strengthening the action of the other." Dr. Ferguson adds, "However, it makes no practical difference, and it is simpler to suppose the insulated body to be the one centre of force." With this last paragraph I cannot agree, as it will be found that, by considering problems of electrostatics by means of the theory of inductive circuits, many can be solved which cannot be explained by an allusion to the earth as a common reservoir. The experiment with the insulated room is only one of them. I maintain that no electricity is ever lost in the ground or drawn from the ground as a reservoir. All electricity generated, if we consider it as a quantity, is produced in equal quantities, and can only be neutralized by an equal quantity of electricity of the opposite name. Thus, when the sphere in the insulated room experiment was charged positively from the prime conductor, an equal quantity of negative went to the room. When the sphere was taken out of the room, this negative went to the outside of the room at the same time that the external conductors to the room became polarised, so that there remained on external objects a charge of negative opposing the positive on the sphere, and a charge of positive opposing the negative on the external surface of the room. By connecting the sphere to the earth, the sphere's charge and its oppposing charge on surrounding objects neutralise each other, leaving the room negative to a positive charge in the earth, which, when touched together, neutralise each other. Or if the sphere is touched to the room, the positive of the sphere neutralises the negative on the room, the negative and positive charges in surrounding objects at the same time recombining also. Or when the sphere was taken back into the room, the negative returned to the inside of the room, the positive and negative which were induced on external conductors by the sphere and room when the sphere was external to the room recombining.

Circumstances prevented Mr. Webb from carrying out a more complete series of experiments, but the experiments made seem sufficient to show the fallacy of the generally accepted theory of the Electrical Machine.

ORIGIN OF ELECTRO-MAGNETISM.

The experiments of Volta resulted in the pile named after him. Two heterogeneous metals, such as zinc and copper, are immersed in a glass of water, to which a few drops of sulphuric acid have been added; both metals we connect by a long wire, and then we find the wire possessed of a new force which can transmit a motion through the distance of a hundred miles and over. For a long time, the Voltaic pile had been the subject of unsuccessful experiments for the purpose of finding its relation to the magnet, to which, on account of its poles, it bears a certain resemblance. One day, Oersted, at a lecture in Copenhagen in 1819, noticed that a magnetic needle on his table was disturbed by a communicating wire that happened to pass over it. He removed the wire, and the needle resumed its polar direction; he then replaced the wire, and the needle again turned aside.

Electro-magnetism was thus discovered. At once he recognized the immense bearing of the phenomenon, repeated the experiment in presence of the magistrate, a notary public and other witnesses, and made a Latin affidavit; this places his name, for all time to come, among the benefactors of the human race. The advantage of his invention is enjoyed by all of us who daily read telegrams from distant parts of the world, as if this rapid transmission of news were a matter of course. The wonder has become a fact of daily occurrence; it rises with us and accompanies us through the day.

SOLAR ECLIPSES AND MAGNETIC VARIATIONS.—In reference to the question of a possible connection between solar eclipses and terrestrial magnetic variations, as deduced from the observations of December, 1870, M. Broun states that a comparison of observations made at Trevandrum (near the central line of the eclipse of December, 1871, on that occasion), with other observations, indicates that ordinary slight magnetic disturbances, passing from one region to another, do not appear to undergo any change of character, either before, during or after an eclipse. And hence he concludes that solar eclipses have not the influence in producing terrestrial magnetic variations that Diamilla Müller and others had assigned to them.

FOREIGN TELEGRAPHIC ITEMS

THE TELEGRAPH CABLE BETWEEN BRAZIL AND PORTUGAL.

As we stated last week, Baron de Itauna, the late Minister of Public Works, a few days before his death, accepted the proposal of Baron de Mana to lay a telegragh cable between Brazil and Europe, on a concession for twenty years. It would appear that Baron de Mana engages to have the cable at work at the end of 1874, and that it will run from some point of the Province of Pernambuco, *via* Madeira and St. Vincent, to Portugal, he having come to an understanding with the English companies holding the Portugeuse concessions for cables between England and Portugal, the arrangements regarding which understanding were approved by the Minister of Agriculture. The decree is dated the 16th August. At the expiration of the twenty years the concessionary will have the use of the cable or cables for twenty years more, but without monopoly. If on January 1, 1885, the number of telegrams during the two previous years should have averaged daily 300, of 20 letters each, the conces ionary may be required to lay a second cable. The charge per telegram of twenty words may not exceed 140f. from the coast of Brazil to that of Portugal, 125f. to Madeira, and 80f. to St. Vincent. If, on or after January 1, 1877, the daily average of the two preceding years should have been 150 telegrams of 20 letters, the rates must be reduced respectively to 120fr., 107fr., and 72fr. 50c. The Government will abate 20 per cent. from its rate for telegrams having to pass its lines to the cable. The concessionary may, before 1877, lay cables to the West Indies and Senegal, and may also lay cables along the coast to points authorized by the Government, should the concession of March 28, 1870, not be carried out. The Cuzco took to England Mr. Rieke, who is commissioned by the directory of the Platino-Brazilian Telegraph Company of Rio Janeiro to place the contract for laying the telegragh cable from Rio to the River Plate, the concession for which is now held by the company.—*The Railway News.*

THE manufacture of the duplicate French Atlantic and of the Great Western cables is steadily progressing; of the former about 700 miles are already coiled on board the Great Eastern, and the electrical condition of the cable is all that can be desired.

THE new General Post-office in London is approaching completion, and steps are being energetically carried out for the transfer of the head telegraph station there; wires are being laid in every direction, and a large system of pneumatic pipes laid down.

AT a meeting of the Board of the Anglo-American Telegraph Company, held October 5th, it was resolved to pay the usual interim dividend of two per cent. on the 1st of November next, for the quarter ending the 30th of September last.

THE directors of the French Atlantic Telegraph Company have declared the usual interim dividend of 2 per cent., payable on the 1st of November next, for the quarter ending September 30.

THE directors of the China Submarine Telegraph Company have declared an interim dividend of 3s. per share for the three months ending the 30th of September, 1872, and they announce that on and after the 15th inst. the rate for messages from London to China will be raised from £4 6s to £6 per twenty words, and to Japan from £5 6s. to £7.

THE Exchange Telegraph Company (Limited) have recently announced that they are now prepared to furnish the offices of subscribers with their telegrapic printing instruments, which will occupy not more than 11 inches of space, and will register the fluctuations of the stock and share markets continuously throughout the day; the system has been at work successfully in America for the last five years, and there are about 300 instruments now in operation there.

POST OFFICE TELEGRAPH.—Statement showing the total number of messages forwarded from Postal Telegraph stations in the United Kingdom during the week ending the 28th of September 1872, and during the corresponding week of 1871. Week ended September 28, 1872, total number of messages, 314,220; week ended September 30, 1871, total number of messages, 270,632; increase in the week of 1872 on that of 1871, 43,588.

The total number of messages forwarded from postal telegraph stations in the United Kingdom for the week ended October 5th, 1872, was 320,231—an increase over the corresponding week of last year of 46,932.

A MEMORANDUM from the London office of the Great Northern Telegraph Company states that the traffic receipts on the company's lines were as under, viz: China and Japan lines—August, 1872, 76,855fr., against August, 1871, 55,912fr. The Shanghai-Nagaski line was opened on the 12th August, 1871. During August, 1872, the Hong-Kong-Shanghai line was interrupted fourteen days. European lines—September, 1872, 131,972fr., against September, 1871, 98,820fr. China and Japan lines—September, 1872 98,490fr., against September, 1871, 41,750f.

THE Australian telegraph line is completed, and communication is now open with Melbourne.

A despatch from that city, dated the 21st inst., was published on the morning of the 22d in London, but it contains nothing of importance.

IN the Spanish Cortes, October 21st, 1872, Senor Pascual called attention to what he termed "the shameful condition of the telegraphic service in Spain." He knew of cases in which despatches from Madrid were forty-eight hours in reaching Paris, and thirty-six hours on the way to Barcelona. He wanted to know if the government, which had charge of the telegraphs, was unable to do better, whether the business could not be transferred to private hands.

THE director of the International Telegraph Office at Berlin has been instructed by the Italian minister to communicate to all the governments and companies represented at the Telegraph Congress held last Winter at Rome that, with the exception of Persia and Denmark, all the parties interested have ratified the convention.

SINCE the opening of the Russian telegraph to the Amoor, and its extention to the China and Japan lines, the number of messages forwarded has increased in such an unexpected and unprecedented manner that the Telegraph Department has resolved to put up another wire on the Siberian line, and the needful orders have been given for the supply of the materials, and the commencement of the work on the section between Omsk and Tomsk as soon as the weather will permit, next Spring.

THE second section of the Russian Telegraph line to Turkestan was opened on the 12th of September from Semipolatinsk to Surguipol, and is found to work admirably.

A COMPANY has been formed for the construction of a telegraphic cable from Rio de Janeiro to the River Plate. A recent report presented by the directors stated that the sea distance from Rio de Janeiro to Lobos Island, off Moletonado, at the mouth of the River Plate is 1,260 miles, and a few more miles of cable will be required from the island to the main land. The shore once reached, a land line of 90 miles will establish communications with Monte Video. Monte Video is connected with Buenos Ayres by a cable, and from the Argentine capital a message can be sent quite across South America, the Andes included, to Valparaiso on the shores of the Pacific. The capital of the Rio Janeiro and River Plate Telegraph Company has been fixed at £600,000, and the work is to be pressed forward with vigor.

THE extension of the telegraph from Grahamstown to Coromandel in New Zealand is nearly completed.

TELEGRAPHIC communication is now complete between Yeddo and Nagasaki, in Japan. Further extensions are in progress.

STATEMENT OF THE TELEGRAPHIC SYSTEM IN HOLLAND FOR 1871.

I. LINES.		
Length of lines in miles		1,939
Length of wire in miles		6,697
II. OFFICERS.		
Offices open for home and international service		261
Of which were Government offices	129	
Of railroad or private companies	132	
		261
Of these, in permanent service there were	3	
Full day service	50	
Limited service	208	
		261
III. APPARATUSES.		
Number of apparatuses in service:		
Morse System	294	
Hughes system	21	
		315
IV. PERSONNEL.		
Upper employés, and of the Central Administration	18	
Number of office employés	611	
Subaltern personnel	246	
		87
V. MESSAGES.		
Interior service, messages sent		1,180,185
International service:		
Messages sent abroad	287,885	
Received from abroad	299,365	
Passing in transit from one frontier to the other	270,912	
Total number of messages		2,038,347
VI. RECEIPTS.		
Product of home correspondence	$147.187	
Product of international correspondence	114,904	
Total receipts		$262,091
VII. EXPENSES.		
Extraordinary Budget:		
Construction of lines	$ 28,079	
Ordinary Budget:		
Expenses of operation and repairs of the lines and offices	355,502	
Total expenses		$383,581

AN official report, which has appeared in illustration of the Victorian Telegraph department for 1871, presents several features of interest. The revenue increased in 1871 to the extent of £4,000, as compared with 1870, and since a uniform shilling rate came into operation the business has been nearly doubled.

CORRESPONDENCE.

To the Editor of The Journal of the Telegraph:

Some time since the JOURNAL said that managers are not *compelled* to write messages if asked to do so by persons who can write themselves; that they should inform all such that they are not authorized by the Company to do so. Now we wish to ask are managers *forbidden* to write telegrams for those who can write?

Often times the senders of messages write almost illegible hands, many cannot spell one word in ten correctly, others do not know where to put address or signature, and sometimes the messages are brought from out of town on slips of paper in no kind of shape to put on file. What shall we do in such cases? Rewrite the messages (a kindness to ourselves as well as the sender,) or send and file as originally written, after making all corrections possible?

Answer.—No manager is forbidden to write telegrams for any one, but any message so written should be signed by the sender. In case a manager or receiving clerk copies an illegible message for the convenience of the operator transmitting it, the original should be attached to and filed with the copy.

To the Editor of the Journal of the Telegraph:

"I notice in the JOURNAL tariff circular of Oct. 1st, 1872, the entry "368 Mounds, Ills.," no county given. There is a "Mounds" in the northern part of the State, for which this is doubtless meant. There is and has been for years, an office at Mounds, Pulaski county, Ill., the business for which is checked with Pulaski, Ills., probably in square 329, as it is between Cairo and Pulaski, as we frequently repeat business to the Pulaski County Mounds, which he claims is not for his office. A correction in the next circular would be of service to the Company and the public."

It will be observed by referring to the tariff circular that the suggestion of our correspondent has been carried out.

To the Editor of the Journal of the Telegraph:

Will you please inform me through the JOURNAL whether I ought to take a message sent "red" from starting point, after seven o'clock A. M.? Should it not have been sent the night before, or else checked full rate? Such are offered me very often.

A YOUNG REPEATER.

The receiving operator has no discretion in the matter. It is his duty to receive all messages sent to him. If he considers any of them improperly sent he should promptly report the matter to his Manager or to his Superintendent.

To the Editor of the Journal of the Telegraph:

I wish to inquire in regard to a message received for collection, and party refuses to pay charges, shall I deliver the message whether he pays or not?

Some claim that they have a right to the message, and I must collect of the party sending the message. I find no rule to apply to such cases. An early answer will oblige OPERATOR.

Answer.—Every message should be promptly delivered, whether paid or collect. If the party receiving a collect message refuses to pay the charges upon it, the fact that he refuses should be promptly reported to the sending office.

Rule 11 provides that all messages, except answers or those covered by franks, must be prepaid, unless guaranteed by responsible parties. Any office which sends a collect message, unless it is an answer, becomes liable for the tolls, and must account for them in case of a refusal to pay by the party to whom it is addressed.

No such message, therefore, should be withheld in consequence of a refusal to pay the charges.

To the Editor of the Journal of the Telegraph:

Referring to Section 3, Ex. Order No. 141, Journal, Sept. 16th, 1872, how should the additional half of the charges collected on a "Red" message, delivered the same night it is received, be accounted for?

Should the sending office be notified to check; or should it be reported as "Extra Receipts"?

Answer.—The amount so collected should be returned as extra telegraph receipts.

To the Editor of the Journal of the Telegraph:

In your issue of August 15th, 1872, I found answer to my query in regard to message received August 1st, dated San Francisco, July 31st. In your issue of Oct. 1st, I see you give me a slight hit in regard to making out my reports as soon as my light was out. This waiting until the night of the 2d, to make out reports, is very nice, provided you have your own way about it. But when the Superintendent orders your reports to be sent in on the 1st without fail, will you please tell me how I am to wait for delayed business? It would, indeed, be very nice to have a word to say once in a while, and to wait for delayed business. REGISTER.

Rule 64 provides that a monthly report of the business of each office must be made at the close of each month, and be forwarded to the District Superintendent not later than the third day of the next succeeding month.

The proper inference to be drawn from this rule is that the first and second day of the month is to be given to the Manager to make out his reports, and post in delayed business.

The book of rules is the guide for all employés alike.

Under date of Omaha, Neb., Oct. 24, we have the following interesting statement:

"Some three months ago, a man riding on the prairie west of here, was struck and instantly killed by lightning. He had upon his person a valuable watch, which was apparently not harmed, but which afterward would not run. A jeweler, on examination, found every steel part of it so strongly magnetized, that where any two steel parts of it come near together, they will not move. He brought me a small piece of the works, containing no more metal than there is in a *small* needle; yet it was so powerful a magnet as to move readily a small galvanometer needle an inch.

"I would like to enquire whether this magnetism can be driven out in any way but by heating, which I think would render the parts magnetized useless."

The parts might be demagnetized by touching them to the poles of a magnet; but the operation would be a difficult one, and would require considerable care. It would be necessary to ascertain the location of the north and south poles in each part, and when touched with a magnet, care must be taken that the contrary charge should not be greater than the charge to be overcome.

THE following, from an indignant correspondent contains a few pertinent enquiries:

"As 'C' was among the offices to which the wrong square was printed in two successive tariff books, I have had ample opportunity to discover the fact that a large number of offices have entirely neglected the important duty of posting their tariff books from the JOURNAL. On behalf of this office, as well as others which have been incorrectly entered in tariff books, and subsequently corrected through the JOURNAL, I respectfully ask whether there cannot be such a penalty attached to this culpable neglec as will make it to the *interest* of these careless parties to keep their tariffs promptly corrected from the JOURNAL. In reply to check error requests received since the distribution of the tariff supplement of September 16th, 1872, three or four have declined to give vouchers for overchecks, because 'both the old and new tariff books show in square 339 and not 329.' This shows that the writers of said replies have made no corrections in their tariffs since 1869! Ought not such men to be forced to pay for their neglect!"

The matter alluded to by our correspondent is a highly important one. All managers should promptly post in their tariff books the changes published in each issue of the JOURNAL. Negligence in this matter can no longer be tolerated.

F. H. Z. We are much interested in your valuable communication, and have no doubt that its publication would be followed by very great benefits, but we think it would be more appropriately published in a medical journal.

The great essentials to be observed by those in the employ of the Company, who are steadily engaged at the desk or table for several hours per day, are plain food, fresh air, and exercise. All stimulants of every character except that derived from the inhalation of pure air, should be avoided. Every man and woman employed in the telegraph business ought to walk at least four miles per day in the open air. If this course is pursued there will be much fewer cases of headache, coughs, colds, and consumption to be found in our ranks.

Another excellent thing for all persons, and especially for those of sedentary occupations, is a cold water bath every day. Cold water, plain food, pure air, and plenty of exercise, will ensure good health even to those whose occupations are of the most confining and sedentary character.

J. S. P. Vine-dresser is one word.

M. P. Managers pay the postage on the JOURNAL recived by them, and charge the amount in their monthly statement.

OPELIKA.—Nothing would be gained by your suggested addition to the sounder in order to prevent waste of local battery. Precisely the same result would be attained if one of the wires were detached from the binding screw in its present form, or if metalic connection was prevented between the points on the relay.

A WELL-CULTIVATED EAR.

One of the most remarkable illustrations of the power which a telegraphic operator acquires to distinguish individuals by their touch upon the instrument, has just been afforded by Mr. Hempstead, one of the operators in the Western Union Telegraph Company's office in this city. About a fortnight ago, Mike W. Sherman, formerly an expert and well-known telegraph operator here, escaped from the Middletown Insane Asylum, where he has been confined, and though thorough search was made for him, he successfully eluded the people who were on his track until Monday night. While Hempstead was at work in the office here that night, he suddenly recognized, among the clatter of a score of messages passing over the wire, a sound which he at once declared was the touch of the missing Mike. It proved to be a message from Wallingford, and an investigation showed that Mr. Hempstead was quite right in ascribing it to the insane man, who was found there yesterday, he having dropped into the office in the former place Monday night, and taken a hand at his old business.—*Hartford Post, Oct. 2.*

Western Union Telegraph Company,

145 Broadway, New York.

NEW YORK, NOVEMBER 1, 1872.

WHEATSTONE'S AUTOMATIC & STEARN'S DUPLEX TELEGRAPHS.

We reproduce in another part of our paper, a concise and exceedingly interesting description of Wheatstone's Automatic Telegraph, read by Mr. R. S. Cully, Engineer-in-Chief of the Post Office Telegraphs, before the Society of Telegraph Engineers. Professor Sir Charles Wheatstone, the inventor of the above mentioned system, stands at the head of the profession as an electrician and inventor of telegraphic apparatus. As the inventor of the Needle Telegraph, the Dial Telegraph, the Wheatstone Balance, and of the best automatic telegraph ever produced, his name will be always associated with the telegraphic progress of the age.

Wheatstone's Automatic Telegraph—unquestionably the most rapid and effective apparatus of the kind which has ever been brought out—has had the singular good fortune of falling into intelligent, appreciative and competent hands. From the first, it has been an especial favorite of the Postal Telegraph authorities. Born in the days of private telegraphy in England, it had met with little favor from the managers of private companies, and seemed likely to die in its infancy without an opportunity of developing its practical capacity. The advent of governmental rule afforded the desired opportunity. As soon as Mr. Scudamore obtained control of the English lines, he ordered a thorough trial of this system Fortunately for both, Mr. Culley, the Engineer-in-Chief of the Postal Telegraphs, is not only one of the most experienced and competent electricians and telegraphists in the world, but he is an enthusiastic admirer of Wheatstone's invention.

Thus, then, the automatic system in England possesses the best possible combination of circumstances for success. The invention of the most distinguished electrical discoverer now living; its practical developement in the hands of one of the most experienced telegraphic engineers in the world, owned by a government with unlimited means at its disposal, and operated in the most wealthy and populous commercial country in Europe, it cannot fail of producing the best results of which the automatic system is capable. What are these results? The answer to this question is perhaps best presented by the distinguished gentleman who participated in the discussion of Mr. Culley's paper at the meeting of the Society before which it was read. At that meeting the following facts were brought out.

The highest speed attained in practice with the Wheatstone apparatus was 120 words per minute, between London and Liverpool, and 38 words per minute between London and Cork.

To operate the automatic apparatus at the rate of 120 words per minute requires eight clerks at each end of the line, consisting of three punchers, one person to attend to the apparatus, and four copyists.

Mr. Culley said that it did not pay to use the automatic apparatus on short lines; it was cheaper to put up extra wires.

Mr. Preece claimed that it was more accurate than handwriting, and consequently produced more speed, because want of accuracy caused a repetition of messages, and thereby delay. On the other hand, the automatic system possessed the following disadvantages:

"The act of punching, the act of preparing the message, and the various processes it had to go through before it passed through the transmitter, involved delay, and the result was that the messages transmitted by these means invariably incurred delay; trifling when taken in the aggregate, but which could not be admitted in short circuits. The next point to be considered with this system was that of expense in regard to the number of persons employed. The average, as far as his experience went, over the numerous automatic circuits they had, was five clerks. What did that mean? It meant that, to increase the capacity of their wires to from 30 to 35 words per minute to 60 or 70 words—which was the average velocity of the automatic system—they must increase the staff from two clerks to ten. Now clerks, they knew, could not live on nothing, and that meant expense, and, as he had shown, the increased capacity of the wires was about double. This problem, therefore, arose. Taking, on the one hand, the double capacity of the wires and its increased staff, and on the other hand, the ordinary working apparatus with its small staff, how far were they justified in doubling the working by the introduction of the automatic wire, or for how short circuits were they justified in adding to the wires instead of applying that automatic apparatus. The practical solution of the problem was this, that the automatic apparatus, economically speaking, could not be applied to less distance than 200 miles. Within that distance it was better to increase the number of wires. Beyond 200 miles it was better to employ the automatic apparatus."

The distance from London to Liverpool, where a speed of 120 words per minute is attained, is 206 miles. The distance from London to Cork, where a speed of but 38 words per minute can be reached, is 482 miles, 62 of which is cable. The highest speed attained between London and Aberdeen, a distance of 515 miles, is 60 words per minute, which is the maximum speed attained in this country upon the Phelps letter printing instrument. Thus then we find that the usefulness of the automatic system, in point of speed as compared with our hand sending apparatus, lies between distances of 200 and 500 miles of aerial wire.

With the Stearns' duplex telegraph we transmit messages in opposite directions at the same time upon a single wire between New York and Chicago, a distance of 1,000 miles, at full speed; or from 70 to 80 words per minute. This apparatus requires no previous preparation of the messages, and consequently neither delay nor extra expense. It is operated by the same operators employed to work the ordinary Morse instruments, and whenever the business is insufficient to occupy a sending and a receiving operator at each end of the wire, the apparatus can be used as a single Morse instrument without change or modification. We are successfully employing this apparatus upon circuits extending between New York and Chicago, New York and Buffalo, New York and Baltimore, New York and Boston, New York and Portland, New York and Albany, Cincinnati and Pittsburgh, Cincinnati and Cleveland, Cincinnati and Chicago, Chicago and St. Louis, Sacramento and San Francisco, and Detroit and Chicago, and have the instrument now in readiness to place upon several additional circuits.

Between New York and Boston we have two sets of the duplex telegraph in operation, and during the season at the watering-places successfully employed them between New York and Long Branch and New York and Saratoga.

When these instruments are supplied to all the great centres of communication, we shall be able to double the capacity of all of our through wires at a moment's notice, and this without the necessity of employing, as in the case of the automatic system, a large and expensive auxiliary force. The great advantage of the Stearns duplex telegraph over the Wheatstone and all other kinds of automatic telegraph lies in its simplicity; in its always being ready for work; in its not requiring an auxilliary force; in its not requiring any previous preparation of messages; in its not causing any delay; in its being operated by the regular force of employés; in its being adapted alike to long or short circuits; in its ability to work through repeaters; in its cheapness; and, finally, in its thorough adaptability to the requirements of all telegraphic correspondence, viz: the instant and constant transmission of messages between any two points, near or remote.

The claim that is set up for the automatic system of less liability of mistake in transmission, is an important one, and, should it be verified in practice, would be entitled to great consideration, for accuracy is a great *desideratum;* but as the messages have to be prepared by hand, and read from the slip by the eye, and then copied by hand, we do not comprehend why there should necessarily be an increase in accuracy.

An experience of twenty years in reading by sight and by sound has produced the almost unanimous conviction in the minds of American telegraphists of the superior accuracy of the latter.

In Mr. Scudamore's report to the Postmaster-General, dated May, 1872, he gives a return of the work done by one Manchester Wheatstone circuit in each hour of the day between ten A. M., and eight P. M., on the 10th of January. The number of messages transmitted per hour range from 31 to 137; the distance from London to Manchester is 227 miles—somewhat less than that between New York and Boston—while the greatest number of messages transmitted is less than has been sent over one wire in the same time with the Stearns duplex apparatus.

We shall watch the progress of automatic telegraphy in England with interest, and should it develope any points of superiority we shall not be slow to acknowledge them. But, so far, we believe that the plan so ingeniously and successfully worked out by Mr. Stearns for increasing the capacity of the wires for the transmission of messages is vastly superior to all others.

With the issue of the Journal of November 15th a large nuuber of subscriptions will expire. It is hardly necessary to expatiate on the excellence of the paper, nor upon the low rate at which it is published. It speaks for itself. We are convinced that every person who now subscribes will continue, and will, upon receipt of this notification, duly apprise us of that fact.

BACK NUMBERS OF THE JOURNAL WANTED.

Numbers 16, 19, 20 and 22, Volume II of the Journal of the Telegraph are wanted to complete a file. Twenty-five cents a number will be paid, and the favor duly appreciated. They may be sent to this office.

PROFESSOR TYNDALL'S FIRST LECTURE IN AMERICA.

Professor Tyndall made his debut before an American audience on the evening of October 15th, in the hall of the Lowell Institute, on Washington street, Boston. It was packed with people, and his reception was exceedingly warm and hearty.

Professor Tyndall's apparatus was arranged chiefly upon a large table, arranged as three sides of a square, in the center of which he stood while speaking. A long, narrow bridge was built out from the front of the platform over the heads of his audience, and on this was placed the auxiliary instruments with which the Professor produced his most brilliant effects, in analyzing a ray of light upon a canvas at the back of the platform.

While his two assistants were preparing the batteries and wires and electrical lamps and prisms, he gave a little discourse on the pursuit of science for the truth's sake, vindicating the investigator and claiming for his apparently aimless labors an importance equally as great as the practical work of the worldly without the scientific experimentalism of 300 years ago. He showed there could be no industrial England or industrial America to-day without such labors. Next he spoke of the importance of the work of the scientific demonstrator, and then turned to his instruments. His lectures, he said, were to be confined to the exposition of the laws of heat and light.

By the aid of a platinum wire and battery, he explained the electrical light which he uses in all his experiments. Bidding the gas glare begone, he caused a platinum wire, stretched across the table in front of him and no thicker than a horse hair, to glow with an intense brightness and then melt by electricity, which sufficed to demonstrate the principles of electrical action. Then substituting his lamp for the circle of gas jets of the hall, he proceeded by a series of rapid and beautiful experiments to analyze a ray of light. Through a tiny aperture in a bit of tinfoil, he took the single ray and showed the process of combustion and the laws of refraction. Then with a prism he resolved the ray into its component fragments, and afterwatds gave the synthesis of light, by those wonderfully brilliant and marvellously simple methods which have given him a world-wide reputation as the greatest living popular scientific demonstrator.

PROFESSOR J. H. PEPPER.

We are pleased to observe the arrival, in this city, of Professor J. H. Pepper, Director of the Royal Polytechnic Institution of London. He comes to this country on a tour of observation.
